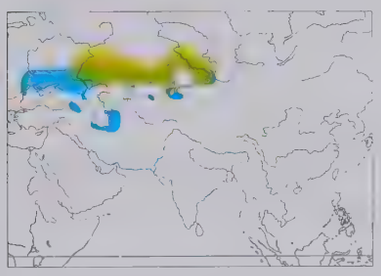
Breeding. Season late Apr/early May to early Aug; number of broods uncertain, conflicting reports of one or two (two more likely in view of drawn-out season). Male low song flight with stiff, slightly downward-bent, angled, quivering wingbeats, may glide on V-held wings when low over ground; high song flight with somewhat quivering beats, now and then interspersed by short glides on outstretched wings. Nest built by female alone, in depression on ground, generally behind tussock or other plant, made from dry grass and *Artemisia*, lined with finer grass. Clutch 3-6 eggs, generally 4 or 5, exceptionally up to 8 recorded; incubation by female, probably assisted by male, period 12-15 days; chicks fed by both parents, leave nest at c. 10 days, fledging period not known.



Movements. Largely migratory. Winters mainly in SW part of breeding range, and from N of Black Sea S through Transcaspia to N Iran. Autumn migration in late Aug to early Nov, mainly Sept-Oct; arrival back on breeding grounds from mid-Mar to late Mar or early Apr, but not until early May in extreme N of range. Vagrants recorded W to Turkey and several European countries (W to Norway and Britain).
Status and Conservation. Not globally threatened. Uncommon to locally common. No reliable population estimates; generally less numerous than other larks occurring in same region. Apparent decrease in numbers and contraction of range recorded in some areas as a result of cultivation of steppe. Was a regular winter visitor to Turkey in 19th century.

68. Black Lark

Melanocorypha yeltoniensis

French: Alouette nègre **German**: Mohrenlerche **Spanish**: Calandria Negra

Taxonomy. *Alauda yeltoniensis* J. R. Forster, 1767, Lake El'ton, south-west Russia.
Monotypic.
Distribution. Breeds in SW Russia and N Kazakhstan from just W of R Volga E to L Zaysan, and S to N shores of Caspian Sea, Aral Sea and just N of L Balkhash. Winters S to Black Sea region, Caucasus, N Iran, Uzbekistan, Turkmenistan and S Kazakhstan.

Descriptive notes. Male c. 20 cm, 56-76 g; female c. 19 cm, 51-68 g. Heavy-bodied lark with rather large bill, quite short tail and fairly broad wings. Adult male is unmistakable: in fresh plumage (autumn) black, with broad buffish feather tips, especially above; pale tips abraded by spring, plumage practically all black in summer; iris dark; bill pale grey, with or without dark culmen or tip of upper mandible, in winter probably more yellowish-tinged; legs dark grey. Adult female in fresh plumage (autumn) is rather pale buffy brownish-grey above with indistinct dark markings, whitish below with buffish breast indistinctly dark-spotted, has diagnostic tertial pattern of rather broad whitish fringe, blackish subterminal band, and broad buffish submarginal area with blackish anterior border; in worn plumage, heavily streaked above and below (including belly), looking very dark overall; throughout year, head pattern rather indistinct, and no prominent pale patterns in wings and tail in flight. Juvenile is similar to moderately worn adult female, but has distinct pale buffish or whitish feather fringes and dark subterminal bands above. Voice. Song, from ground or, preferably, low perch such as bush, or in flight, a sustained rapid twittering and chirping with interspersed softer, more plaintive notes, like that of e.g. *M. calandra* but strophes shorter and vary more in tempo, strength, pitch, type of notes etc. Calls with various short, harsh notes, reminiscent of e.g. *M. calandra*.
Habitat. Steppe (with e.g. *Artemisia*, *Stipa*, *Festuca*), preferably with some bushes, often in wet patches. Also on patches of such habitat in saline semi-desert.
Food and Feeding. Invertebrates and seeds. Diet in summer reported as mainly invertebrates, especially orthopterans and adult and larval beetles (Coleoptera), but also e.g. bugs (Hemiptera), lepidopterans, flies (Diptera), hymenopterans (chiefly ants), spiders (Araneae) and myriapods, also some seeds and other plant material (e.g. *Festuca*, *Stipa*, Chenopodiaceae, Polygonaceae); according to other reports, more seeds (especially of *Polygonum* and *Rumex*) than invertebrates taken in summer. In winter, feeds exclusively on seeds. Forages on ground, in flocks outside breeding season. In winter, when ground snow-covered, seeks seeds by digging down to c. 8 cm, also by creating channels and tunnels up to 20 cm long in snow; also said to follow horses and to take food items exposed by them.
Breeding. Season late Mar to Aug, starting at least one month earlier in S than in N; number of broods uncertain, but length of season suggests that two more likely. Male aerial display spectacular, in high song-flight flies as if slowly "rowing", with fully extended and raised wings and fanned tail, or alternates between normal wingbeats and short or longer glides on spread wings and tail; in low-level display, ordinary flight interchanging with spells of slow, large-amplitude beats (may then clap wings) and short glides on raised, often trembling, or depressed wings. Nest built by female, in depression on ground, usually under tuft of grass or other plant, made from *Artemisia* or grass, lined with finer grass, site often surrounded by animal dung. Clutch 2-8 eggs, most often 4 or 5; incubation by female alone, period 15-16 days; chicks fed by both parents, leave nest at 9-11 days, fledging period not documented.
Movements. Resident or short-distance migrant; probably also to some extent nomadic. Some move S or SW, beginning in Sept and Oct, reaching Ukraine, Black Sea region and extreme S parts of European Russia, and S to Caucasus region, N Iran, Turkmenistan and Uzbekistan; a few also move N, NE and NW. Adults usually form single-sex flocks in non-breeding season. Recorded as accidental in several European countries (W to Britain, N to Sweden and Finland), also Turkey, Lebanon and Mongolia.
Status and Conservation. Not globally threatened. Locally common. No accurate figures for population; possibly 6000-10,000 pairs estimated in Russia. Has apparently decreased locally in Kazakhstan, possibly also in Russia, as a result of cultivation of dry steppes; steppe habitat elsewhere in range also threatened by intensification of stock-farming. Sex ratio of this species exceptionally skewed, males outnumbering females (e.g. 68% of fledged juveniles in one study were males); in non-breeding season, male flocks often large but those of females much smaller; flocks consisting solely of males often encountered also at peak of breeding season.

Genus *CALANDRELLA* Kaup, 1829

69. Greater Short-toed Lark
Calandrella brachydactyla

French: Alouette calandrelle **German**: Kurzzehenlerche **Spanish**: Terrera Común
Other common names: (European) Short-toed Lark

Taxonomy. *Alauda brachydactila* [sic] Leisler, 1814, Montpellier, France.
May form a superspecies with *C. cinerea*, with which often merged, and with *C. blanfordi*, *C. erlangeri* and *C. acutirostris*. Geographical variation slight and clinal, generally becoming paler and greyer to E, more rufous and streaked above to W, but greatly complicated by strong influence of wear on plumage, considerable individual variation and lack of natural boundaries; described ranges of listed taxa somewhat arbitrary. Further, races *artemisiana*, *hermonensis* and *woltersi* all intergrade in S Turkey; birds from Ukraine are intermediate between nominate race and *longipennis*, and those from Ural-Volga steppes, the Caucasus, E Iran and N Afghanistan between latter race and *artemisiana*. In addition, populations from E Altai and S Siberia have been separated as race *orientalis* and those from NW Manchuria as *puii*, but differences from typical *longipennis* seem to be minor. Validity of race *hungarica* sometimes disputed, mainly on grounds that tiny population is apparently boosted by periodic influxes from elsewhere. Eight subspecies currently recognized.
Subspecies and Distribution.
C. b. brachydactyla (Leisler, 1814) - breeds Europe from W, NC & S France and Iberia E (including many Mediterranean islands) to Italy, the Balkans and Romania (possibly to Ukraine and S Russia), apparently also in some parts of Mediterranean coast of NW Africa; winters Africa.
C. b. hungarica Horváth, 1956 - breeds Hungary and N Serbia (Vojvodina), possibly also S Slovakia.
C. b. rubiginosa Fromholz, 1913 - breeds NW Africa from Morocco and N Western Sahara E to NW Libya (W Tripolitania); also Malta.
C. b. hermonensis Tristram, 1865 - S Turkey and Syria S to NE Egypt (Sinai Peninsula).
C. b. woltersi Kumerloeve, 1969 - S Turkey (Amik Gölü, Gaziantep, Birecik) and adjacent extreme NW Syria.
C. b. artemisiana Banjkowski, 1913 - breeds Asia Minor, the Caucasus, Transcaucasia and Iran; winters mainly SW Asia.
C. b. longipennis (Eversmann, 1848) - breeds Ukraine and S Russia E to N Mongolia and NW Manchuria; winters mainly S Asia.
C. b. dukhunensis (Sykes, 1832) - breeds Tibet and C China; winters S Asia.

Descriptive notes. 14-15 cm; c. 20-26 g. Small, neat, pale, short-billed lark with long tertials almost cloaking tips of folded wings, narrow and pointed outer primary strongly reduced (7-11 mm short of primary-covert tips), shortish tail; straight hind claw 7-9 mm long. Nominate race has broad whitish supercilium, grey-brown cheeks; warm brown to grey-brown and heavily streaked blackish above, top of head usually densely streaked and often rufous-tinged, with erectile feathers; median coverts with dark centres and buff fringes, contrast with rest of upperwing; tail blackish-brown, centre brown, white outer feathers; throat and underparts whitish, small blackish patch on lower neck side (often obscured in fresh autumn plumage), breast side with faint buff tinge and fine dark streaks (variable, often whitish and unstreaked); undertail blackish (noticeable in flight); bill pale horn-coloured, darker culmen and tip, yellowish on lower mandible; legs pale brownish-flesh to light brown. Sexes similar. Juvenile resembles adult, but upperpart feathers dark brown with buff fringes and whitish tips, outer primary longer (1-6 mm short of primary coverts) and tip more rounded. Races differ mainly in plumage tone above, but greatly affected by influence of wear, and following is only a general guide: *hungarica* is buffer and greyer than nominate; *rubiginosa* is more rufous, especially on crown, also more finely streaked; *hermonensis* is less rufous, more buff, than previous, with crown less contrasting; *woltersi* resembles last, but paler and greyer; *artemisiana* is slightly darker than last, more buffish-grey, also more heavily streaked; *longipennis* is greyish-sandy and finely streaked above, bill relatively small; *dukhunensis* is distinctive, larger, longer-winged and slightly smaller-billed than other races, dark brown and heavily streaked above, buff-washed below, legs dark. Voice. Song, in aerial display, less often from ground, clear and musical but rather monotonous, with accelerating simple notes, then several hesitant notes, and finally a long series of persistently repeated phrases each c. 2 seconds long and consisting of 8-10 bubbling notes, pauses of 2-3 seconds between phrases (coinciding with undulations in flight); imitations of other bird species often incorporated. Commonest call a dry "chirrup" or "dreet", often repeated; also "teeoo" or "trilp".
Habitat. Dry areas with sparse and low vegetation cover, on level or undulating terrain, with sandy or stony soils. Breeds mostly in fallow lands in Mediterranean Basin, but also dry pastures, tobacco fields, dirt tracks and olive groves; in Russia also more densely covered pastures, but absent in true steppe; sometimes in semi-arid areas, but avoids true desert. Mainly lowlands; to 1500 m in Tunisia. Occurs in semi-arid areas and farmland in non-breeding areas.
Food and Feeding. Mainly invertebrates during spring, also seeds and green parts of plants in other seasons. Invertebrate food very diverse, variable among areas, chiefly beetles (Coleoptera), ants, bugs (Hemiptera) and snails; seeds mostly of weedy forbs (*Polygonum*, *Amaranthus*), also cereal grain. Nestlings fed solely with invertebrates; fledglings take more green material than do adults. Forages on ground, singly or in small or large flocks. Searches slowly, picks items from ground surface.
Breeding. Lays in May-Jul in SW Europe and from mid-Apr in SE Europe; from early Apr in N Africa and Israel; two broods per season. Male song flight typically at heights of c. 30-50 m, undulating and bouncing in a circling but rather meandering path, lasting on average 3-5 minutes. Nest built by female, of grasses, rootlets and similar vegetation, lined with softer material, internal diameter 6 cm, placed in shallow scrape on ground, usually beside shrub or grass tuft, often with small rampart of sticks or stones; orientation in Spain mainly to N. Clutch 2-5 eggs, rarely 6 (mode 3 in N Africa, 4 in Spain, 5 in Hungary), clutch size in Spain larger in middle of season; replacement laid if first clutch lost; incubation by female alone, beginning with last or penultimate egg, period 11-13 days; chicks fed and cared for by both sexes, nestling period 9-12 days, mostly 8-10 days, fledging 12-15 days; dependence period of fledglings 1-3 weeks, shorter for first broods. Nest losses often very high, up to c. 80%; snakes a major predator, and some nests also destroyed by trampling by livestock. First breeding at 1 year.
Movements. Mostly migratory; only partially migratory in S of Palearctic range, and sedentary in Transcaucasia. Those from W & C parts of range winter mainly in sub-Saharan Africa (S Sahel zone) and Red Sea Basin, also in SW Asia; E populations migrate mostly to S & SE parts of Asia; highly gregarious on wintering grounds, occurring in flocks of hundreds or thousands. Autumn departure from mid-Aug through to Sept/Oct, passage on broad front; return begins late Jan, but migration later in E, and arrival on breeding grounds in N of range not until Apr-May; generally common on passage in N Africa, abundant in Egypt, and common to fairly common in Middle East and Arabian Peninsula; in S Israel, up to 14,000 per day recorded in autumn (Sept-Oct) and flock of c. 4000 in Apr. Vagrants regularly W to Scandinavia and British Is, and recorded on Madeira and Canary Is, also N to Iceland and regularly Finland; rare but annual in Japan; in S, recorded to Cameroon, DRCongo and Kenya.
Status and Conservation. Not globally threatened. Common to locally abundant in many parts of very extensive range. Estimated European population 2,500,000-3,500,000 pairs, vast majority concentrated in Iberia; widespread and numerous in Spain (in early 1990s 2,200,000-2,600,000 pairs, most in Ebro Valley, S Meseta and Andalucia, but absent in N humid belt), with up to 2-5 pairs/ha in best habitats, and common in Portugal (100,000-1,000,000 pairs, mainly in S); much smaller populations in France (1000-5000 pairs), Italy (15,000-30,000), Croatia (1000-1500), Albania (1000-3000), Greece (20,000-50,000), Bulgaria (5000-10,000), Romania (6000-8000), Hungary (8-10), Ukraine (7000-11,000 pairs); on Mediterranean islands, widespread but not abundant in Balearics, scarce Corsica (tens of pairs), common to fairly common Sardinia, Sicily and Crete, very common to common Malta (2000-3000 birds) and Cyprus (perhaps 5000-20,000 pairs); has bred Switzerland (1989) and E Austria (1966), and regularly S Slovakia since 1992. Estimated Russian population 100,000-1,000,000 pairs, with 2-3 pairs/ha on Russian steppes. In C parts of range, 10,000-100,000 pairs in Turkey (widespread and locally common in W, scarce in E), common in Azerbaijan, scarce in Lebanon, fairly common in Israel (a few thousand pairs), local in Jordan (where relatively dense colonization at Azraq in early 1980s, but no recent evidence of breeding); fairly common in China. In N Africa, common in Morocco, widespread in N Algeria, very common and widely distributed in Tunisia, rather scarce in Libya; scarce in NE Egypt, bred in Wadi El Arish area in 1989 and 1990 (breeding formerly suspected only for Wadi El Natrun, in early 19th century). In African non-breeding quarters widespread in Sahel belt, where locally abundant in Mali, widespread in Niger, and common in extreme NE Nigeria, Sudan (abundant on short-grass plains) and NE Ethiopia; common winter visitor in at least Saudi Arabia, Pakistan and parts of India. Declining, and considered "vulnerable", in Europe, where strong decline and range contraction in France (especially in W); over 20% decrease in numbers in 1970-1990 and perhaps over 30% in 1990-2000 in Spain; main threats from agricultural intensification (leading to loss of fallows, increased number of irrigation schemes, increase in surface area covered by crops, etc.) and afforestation of wastelands. Race *hungarica* threatened with extinction; only 8-10 pairs in Hungary, where numbers in traditional area, the Hortobágy steppe, have declined sharply since early 1980s, although sudden increases in certain years (attributed to influxes from neighbouring populations, hence casting doubts on validity of this race). Reported as causing damage to cultivations of pearl millet (*Pannisetum typhoides*) on wintering grounds in NW India (Rajasthan).

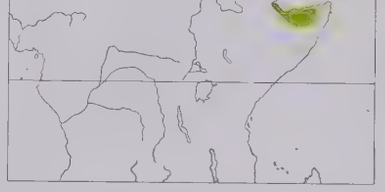
70. Red-capped Lark
Calandrella cinerea

French: Alouette cendrille **German**: Rotkappenlerche **Spanish**: Terrera Capirotada
Other common names: African Short-toed/Rufous Short-toed Lark

Taxonomy. *Alauda cinerea* J. F. Gmelin, 1789, no locality = Cape Town, South Africa.
May form a superspecies with *C. brachydactyla*, *C. blanfordi*, *C. erlangeri* and *C. acutirostris*; often considered conspecific with first three (especially *C. blanfordi* and *C. erlangeri*). Geographical variation among many contiguous races limited and broadly clinal; further study may demonstrate that several taxa are not sustainable. Additional named races are *ongumaensis* (N Namibia), synonymized with *spleniata*, *witputzi* (S Namibia), included in nominate, and *vagilans* (E Botswana and NE South Africa), included in *niveni*; also, description of *anderssoni* (C Namibia) apparently based on worn non-breeding specimen of nominate. Eight subspecies tentatively recognized.
Subspecies and Distribution.
C. c. saturatior Reichenow, 1904 - Nigeria (Jos Plateau), and DRCongo E to Uganda and W & SW Tanzania, S to Angola (except NW & S), N Zambia and Malawi.
C. c. williamsi Clancey, 1952 - S Kenya and N Tanzania.

On following pages: 71. Blanford's Lark (*Calandrella blanfordi*); 72. Erlanger's Lark (*Calandrella erlangeri*); 73. Hume's Lark (*Calandrella acutirostris*); 74. Somali Short-toed Lark (*Calandrella somalica*); 75. Lesser Short-toed Lark (*Calandrella rufescens*); 76. Sand Lark (*Calandrella raytal*).

C. c. spleniata (Strickland, 1853) - SW Angola and NW Namibia.
C. c. fulvida Clancey, 1978 - S Angola, S Zambia and Zimbabwe.
C. c. alluvia Clancey, 1971 - breeds coastal S Mozambique; disperses inland to N Botswana.
C. c. millardi Paterson, 1958 - S Botswana.
C. c. cinerea (J. F. Gmelin, 1789) - S Namibia and W South Africa.
C. c. niveni (Macdonald, 1952) - E South Africa.



Descriptive notes. 14-15 cm; 20-26 g. Medium-sized lark with short, rather weak bill, adult with distinctive brick-red crown and breast-side patch, crown feathers sometimes raised to form prominent short crest; wing shape rather distinctive, with elongate outer primaries and inner secondaries and tertials. Nominate race has white supercilium contrasting with crown, plain brown or buffy face, slightly darker on ear-coverts; upperparts brown with slightly darker feather centres, rump rufous; flight-feathers and tail dark brown with paler buff-brown margins, outer primary and outer tail feathers with buffish-white outer webs, central tail with broad buffy margins (in flight, dark tail and flight-feathers contrast with paler wing-coverts and back); throat, partial collar beneath ear-coverts and underparts whitish, red patch on breast side, flanks variably washed buffy; eyes brown; bill blackish, with paler base; legs flesh-brown to dark brown. Easily distinguished from other larks by entirely red pectoral patches. Sexes alike. Juvenile is darker than adult, back and crown feathers with broad whitish margins and blackish-brown subterminal bars (appearing spotted or scaled above), breast diffusely spotted dark brown, pectoral patches mottled blackish, bill paler. Races differ mostly in upperpart coloration, varying from rather pale sandy-brown or grey-brown to warmer rufous-brown (paler and plainer in more arid areas): e.g. *spleniata* is much paler, pale yellow-sandy, and only lightly streaked; *millardi* is more whitish-grey above; *fulvida* is generally darker; *saturatior* is distinctly brighter, more rufous; *williamsi* is greyer overall, crown and breast patches duller rufous, upperparts darker and more heavily streaked than nominate. Voice. Male song, in flight, a series of simple, rather unmelodic whistles and short trills, may include mimicry of other birds' songs; also subsong with mimicry while foraging on ground, one bird recorded as mimicking in 5-minute period elements from 11 other species, including canaries (*Serinus*) and other finches, sparrows (*Passer*), barbets (Capitonidae), shrikes (Laniidae), weavers (Ploceidae) and starlings (Sturnidae). Loud, sparrow-like "chwerp" often uttered in flight or when flushed.
Habitat. Open grassland and bare ground, including recently harvested or ploughed fields, and edges of wetlands; common in short saltmarsh vegetation at coastal lagoons. Often nests in areas of poorly drained, clayey soils, frequently around wetland margins. In montane grasslands of E South Africa occurs at significantly higher densities on annually burned fields, and slightly more abundant in heavily grazed grasslands; often moves into burned areas immediately after a fire. Mainly short grassland in E Africa, to 3000 m. Frequently encountered on roads and road margins, especially after rain. Apparently flies to bare areas after sunset to roost.
Food and Feeding. Seeds, insects and snails. Stomach contents mostly seeds of grasses and sedges; relatively few insects, e.g. caterpillars, bugs (Hemiptera), grasshoppers (Acrididae), beetles (Coleoptera) and wasps (Hymenoptera), and only *Margarodes* scale insects (which feed on roots but emerge after rains) were frequent. In contrast, only 2% of seeds consumed in the Karoo were of grasses. Takes winged termites (Isoptera) at emergences; also larvae of flies (Diptera) and beetles. Stomachs often contain grit, apparently to aid digestion. Identifiable prey items fed to chicks were invariably insects, including caterpillars and moths (Lepidoptera), grasshoppers, mantids, beetles, fly larvae, ants and termites; roughly half of food brought to chicks is collected outside territory. Forages on ground, singly or in groups, sometimes large flocks outside breeding season. Searches ground for items; often forages in areas with plentiful game, breaking open dung with the bill to obtain larvae. Occasionally undertakes brief aerial pursuits after flying moths or termites. In arid areas, regularly visits water to drink.
Breeding. Associated with rains or just before onset of rains (possibly to avoid nest flooding in poorly drained soils) in most areas, although after rains (Sept-Oct) in SW South Africa; peak in Aug-Oct in E South Africa, extending through to May in NW South Africa and Namibia; Aug-Sept in Zimbabwe and Zambia; Jul-Aug in Tanzania, and Mar-May and Nov-Dec in rest of E Africa; at least some pairs double-brooded, in one case laying in newly built nest 21 days after brood had left first nest. Monogamous and territorial; breeds singly, but often at high densities, inter-nest distance usually at least 50 m, sometimes only 20-25 m. Male vigorously proclaims territory with undulating aerial display like that of a pipit (*Anthus*), rising steeply up to 50 m from ground, then alternately fluttering and diving, singing almost continuously, for up to 10 minutes; sometimes resorts to fights on ground, with threat displays including crouched posture with fanned tail and raised, quivering wings; occasionally chases other species away from nest-site. Nest built mainly by female, in 4-5 days, an open cup, lined with grass and other vegetation, in shallow hollow on ground, usually at base of a shrub or grass tuft, often with "apron" of coarse material (soil, dung, pebbles) on exposed side; in hot, arid areas nests situated predominantly on E or SE side of sheltering vegetation, apparently for shading from afternoon sun. Clutch 2-3 eggs, rarely 4 (mean 2·2), laid one per day; incubation by female alone, fed on nest by male, period lasts 12-15 days; hatching synchronous, suggesting that incubation starts with final egg, parents remove eggshell fragments after hatching; chicks cared for by both parents, female probably doing majority of brooding and provisioning, brooded for up to 7 days, shaded on hot, still days by parent standing over them; during middle of day chicks fed 2-23 times (average 8 times) per hour, average hourly rate of feeds increased with brood size, 4·4 for single-chick nests, 10·8 for two chicks and 13 for three chicks; male tends to make fewer visits but delivers more food on each visit; parents remove faecal pellets from nest rim; adults occasionally feign injury to distract predators, but this rare; chicks remain in nest for 9-18 days, mean 12 days. In South Africa, crude breeding success in one study was 61%, with hatching success 81% and fledging success 76% (but hatching success overestimated owing to failure to include eggs lost before nests found), and in another study, in E grasslands, success much lower, less than 10%; in both studies, predation major cause of nest failure, other causes including starvation of chicks, nest desertion, egg damage by parent, fire, and nest burial by mole-rat (*Bathyergus*) diggings; in one study 2-egg clutches tended to produce greater relative success (1·5 chicks fledged per nest) than 3-egg clutches (2 chicks per nest).
Movements. Poorly understood. Some populations resident; others move extensively, usually in response to local conditions, and some apparently undertake regular migrations. Race *saturatior* is a dry-season (Jul-Oct) breeding visitor to Zambia and Malawi; unclear where this population goes at other times, but may migrate N, perhaps even crossing the equator. Vagrants recorded in N Gabon and PRCongo.
Status and Conservation. Not globally threatened. Common to locally abundant in S, becoming more local and uncommon in N; common but patchily distributed in E Africa; uncommon and very local in Nigeria. Breeding densities of up to 2-4 pairs/ha in South Africa. In non-breeding season, average flock size in the Karoo (South Africa) of 8 individuals, but flocks of up to 100 birds are regular, and rarely even gatherings of thousands. Has probably benefited from human activities in many areas, as often prefers agricultural lands and heavily grazed areas for foraging.

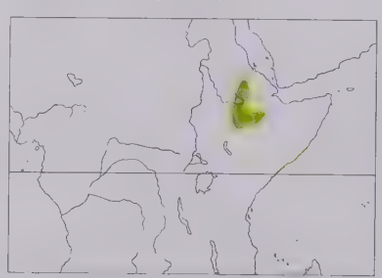
71. Blanford's Lark
Calandrella blanfordi

French: Alouette de Blanford **German**: Blanfordlerche **Spanish**: Terrera de Blanford
Other common names: Blanford's Short-toed Lark

Taxonomy. *Tephrocorys blanfordi* Shelley, 1902, Senafé, Tigré, Eritrea.
May form a superspecies with *C. brachydactyla*, *C. cinerea*, *C. erlangeri* and *C. acutirostris*; often considered conspecific with first three (especially *C. cinerea* and *C. erlangeri*). Three subspecies recognized.
Subspecies and Distribution.
C. b. eremica (Reichenow & J. L. Peters, 1932) - SW Saudi Arabia and Yemen.
C. b. blanfordi (Shelley, 1902) - N Eritrea.
C. b. daaroodensis C. M. N. White, 1960 - N Somalia.



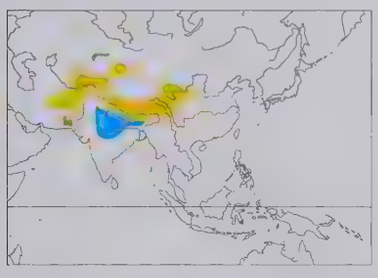
Descriptive notes. 13-14 cm. Medium-sized lark, adult with rufous crown feathers sometimes erected to form prominent short crest. Nominate race has relatively plain face, with whitish supercilium and lores; upperparts rather pale, sandy brown, with darker brown feather centres; rump and uppertail-coverts more uniform tawny-sand; flight-feathers dusky brown, paler buffish-brown margins (broader on inner secondaries and tertials); tail dark brown, central feathers with broad buffy margins, outer feathers with white tips and outer webs; white below, breast and flanks washed pinkish-buff, black patch on breast side surrounded by rich rufous (on some individuals black extends across breast to form almost complete pectoral band); eyes, bill and legs dark brown. Distinguished from very similar *C. cinerea* by black-centred pectoral patches; from *C. erlangeri* by distinctly paler and less streaked upperparts, paler rufous crown without black streaking, typically smaller pectoral patches. Sexes alike. Juvenile undescribed, probably similar to juvenile *C. cinerea*. Race *daaroodensis* is smaller and paler than nominate; *eremica* has darker rufous crown with blackish lateral streak anteriorly, blackish loral streak, yellower bill. Voice. Song (race *eremica*), in flight, described as repeated "chew" notes mixed with call-like notes and more liquid phrases; calls include dry "grlit-drlit" in flight, also "pit-wit-pit" twitter, also "peeeep" and softer "tsru".
Habitat. Open grassland and bare ground, including stony areas. Generally avoids bushed areas in Africa, but found in wadis with occasional bushes and scattered trees in Arabia. Occurs at 600-1800 m in Somalia; in Arabia mostly above 900 m, mainly 1800-2500 m, lower in winter.
Food and Feeding. Mostly small seeds; also a few insects, including grasshoppers (Acrididae) and beetles (Coleoptera). Feeds on the ground.
Breeding. No documented information; nest and eggs unknown. A nest possibly of this species found in N Somalia in Jun, held 6 eggs, but identity of female unconfirmed. In Arabia (*eremica*), male performs circular, slightly undulating song flight.
Movements. Resident, probably subject to local movements. Vagrant reported in Oman.
Status and Conservation. Not globally threatened. Locally common. Often in flocks when not breeding, but no information on size of such gatherings. Poorly known species.
Bibliography. Archer & Godman (1937-1961), Ash & Miskell (1998), Friedmann (1937), Keith *et al.* (1992), Mackworth-Praed & Grant (1960), Meinertzhagen (1954a), Sinclair & Ryan (2003), Smith (1957), Urban & Brown (1971), White (1960b), Zinner (2001).

72. Erlanger's Lark
Calandrella erlangeri

French: Alouette d'Erlanger **German**: Erlangerlerche **Spanish**: Terrera de Erlanger
Other common names: Erlanger's Short-toed/Ethiopian Short-toed Lark

Taxonomy. *Tephrocorys cinerea erlangeri* Neumann, 1906, Sheikh Mehamed, Webi River, Ethiopia.
May form a superspecies with *C. brachydactyla*, *C. cinerea*, *C. blanfordi* and *C. acutirostris*; often considered conspecific with first three (especially *C. cinerea* and *C. blanfordi*). N populations on average slightly paler and are less streaked above, sometimes separated as race *asmaraensis*. Monotypic.
Distribution. Ethiopian Highlands.

Descriptive notes. 13-14 cm. Medium-sized lark, adult with reddish crown feathers that can be raised into prominent short crest. Has plain face, with whitish supercilium and lores; crown rufous, often blackish on forecrown and streaked blackish on hindcrown; upperparts sandy brown, blackish feather centres forming prominent streaks, rump and uppertail-coverts more uniform tawny-sand (in worn plumage appears darker above); flight-feathers and tail dark brown with paler buff-brown margins, broader on inner secondaries, tertials and central rectrices, outer rectrices with white outer webs; white below, breast and flanks washed rufous, becoming darker towards breast side and merging with large black pectoral patch;



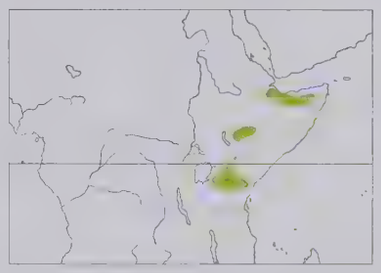
eyes, bill and legs dark brown. Differs from *C. cinerea* and *C. blanfordi* in generally darker appearance, large black pectoral patches, darker crown. Sexes alike. Juvenile undescribed, probably similar to dark juvenile of *C. cinerea*. Voice. Male song, in flight, a series of whistles and short trills, may include mimicry of other birds; flight call a loud "chwerp", like call of sparrow (*Passer*); vocalizations similar to those of *C. cinerea*.
Habitat. Open grassland and fields; often occurs in large numbers on recently ploughed land.
Food and Feeding. Diet unknown; feeds on the ground.
Breeding. Breeds May-Jun. Male has undulating aerial display, rising steeply up to 50 m and then alternately fluttering and diving, while singing almost continuously, for up to 10 minutes; similar to *C. cinerea* display. Nest and eggs undescribed.
Movements. Probably largely resident, but subject to local movements.
Status and Conservation. Not globally threatened. Common. Often in flocks when not breeding, but no information on flock sizes. Relatively poorly known species.
Bibliography. Desfayes (1975), Francis & Shirihai (1999), Friedmann (1937), Keith *et al.* (1992), Mackworth-Praed & Grant (1960), Sinclair & Ryan (2003), Urban & Brown (1971), White (1960b).

73. Hume's Lark

Calandrella acutirostris

French: Alouette de Hume **German**: Tibetlerche **Spanish**: Terrera de Hume
Other common names: Hume's Short-toed Lark, Slender-billed Lark

Taxonomy. *Calandrella acutirostris* Hume, 1873, Sughet Pass, south-west Xinjiang, China.
May form a superspecies with *C. brachydactyla*, *C. cinerea*, *C. blanfordi* and *C. erlangeri*. Two subspecies recognized.
Subspecies and Distribution.
C. a. acutirostris Hume, 1873 - breeds NE Iran E to S Kazakhstan, Afghanistan, Pakistan and extreme W China (W Xinjiang); winters mainly Pakistan and NW India.
C. a. tibetana W. E. Brooks, 1880 - breeds NE Pakistan and NW India E across Tibetan Plateau to C China (S Gansu, extreme W Ningxia & NW Sichuan) and S to Nepal and Sikkim; winters N Indian Subcontinent.



Descriptive notes. 13-14 cm. Small, neat, rather pale lark with long tertials almost cloaking tips of folded wings. Nominate race has white supercilium, and distinct dark loral spot; overall grey-brown or brown-grey above, crown slightly rufous-tinged and faintly dark-streaked (often appears almost uniform), hindneck rather plain, upperparts fairly heavily streaked dark, uppertail-coverts rufous-tinged; wings dark grey-brown, upperwing-coverts and tertials with buffish tips and edges, remiges with narrow pale edges; tail blackish-brown, central feather pair with broad brownish edges, outermost pair with whitish outer web and usually some pale on inner web (sometimes none, occasionally a prominent pale wedge); whitish below, breast washed buffish to more brown-grey, small blackish patch on side of lower neck/upper breast (can be obscured in fresh autumn plumage); bill pale brownish-yellow or greyish-yellow, culmen and tip of lower mandible dark grey; legs pinkish to brownish. Distinguished from very similar *C. brachydactyla* (of greyish race *longipennis*) by less contrastingly streaked crown, dark loral stripe, better-defined whiter and narrower but more contrasting supercilium, usually less white on outer rectrix, usually longer and more slender and pointed bill with yellow coloration and darker culmen; in the hand, 6th primary (numbered descendently) marginally shorter (not considerably shorter) than wingtip, and three (not two) distinct emarginations of primaries. Sexes similar in plumage, female on average smaller than male. Juvenile has distinct whitish fringes and dark subterminal bands above, lacks dark patch on neck/breast side (breast side indistinctly dark-spotted), has shorter tertials than adult (not reaching tip of wing), very similar to juvenile *C. brachydactyla*. Race *tibetana* is paler, greyer and less prominently streaked on upperparts than nominate, also has less marked head pattern, with supercilium generally less distinct, especially in front of eye, dark loral stripe less obvious (can appear to be absent). Voice. Song, mainly in high flight, short strophes of varied short (though often rather complex) notes interspersed with relatively long pauses, resembles that of *C. brachydactyla* but usually slower and includes more whistles and harsh notes; when on ground, or in low flight (or during ascent to high song flight), strophes more irregular and pauses often shorter, individual song elements tend to be shorter than in high flight, and song includes drawn-out whistles (often repeated many times), call notes and sometimes imitations of other birds. Commonest call a dry, harsh, rattling or even rasping "chirr" or "chirrrp", harsher, more rattling and more drawn out than corresponding call of *C. brachydactyla*.
Habitat. Breeds in sandy and gravelly habitats with very sparse vegetation, at elevations of 1000-5000 m. Winters in similar or slightly less barren habitats at low altitudes; often found together with *C. brachydactyla* (of race *longipennis*) in non-breeding season, but usually not in mixed flocks.
Food and Feeding. Food poorly known; seeds and invertebrates. Forages on ground, in flocks in non-breeding season.
Breeding. Little studied. Season mainly May-Aug, chiefly from Jun at higher altitudes; probably two broods. Song-flighting male rises high, and hangs more or less still or circles somewhat, alternating between a few wingbeats and short dipping glides on spread wings and partly fanned tail. Nest, built by both sexes, a depression in ground, generally sheltered by tussock, lined with grass, hair and some moss, sometimes rimmed with gravel. Clutch 2-4 eggs, usually 3; conflicting reports on role of sexes in incubation, either by female alone or by both sexes, period 10-11 days; chicks fed by both parents, leave nest at 10-11 days.
Movements. Migratory. Nominate race winters mainly in Pakistan and NW India; *tibetana* in Nepal, N India, Bhutan and Bangladesh. Leaves Tibetan Plateau at the latest in Oct; present in NW India between late Sept and early May; arrival back on Tibetan Plateau from early Apr, and in W Tien Shan in late Apr to early May. Status in NE Iran requires confirmation, and species might be merely vagrant. Recorded as vagrant in Israel.
Status and Conservation. Not globally threatened. Locally common; scarce in some areas. Frequent to scarce in Pakistan; in India, common in Ladakh but less common in Sikkim; common in NW Nepal; rare to locally abundant in China. Apparently rare in NE Iran and Bhutan, though limited information. No population estimates available.
Bibliography. Ali & Ripley (1987), Alström *et al.* (2004), Dementiev *et al.* (1970), Dickinson & Dekker (2001a), Dickinson, Dekker, Eck & Somadikarta (2001), Étchécopar & Hüe (1983b), Gavrilov (1999), Grimmett *et al.* (1998), Hüe & Étchécopar (1970), Inskipp & Inskipp (1991), MacKinnon & Phillipps (2000), Martens & Eck (1995), Pätzold (1994, 2003), Porter *et al.* (1996), Rasmussen & Anderton (2004), Ripley (1982), Roberts (1992), Shirihai (1996, 1999), Shirihai & Alström (1990), Sinha & Sinha (1984), Snow & Perrins (1998), Stepanyan (1971, 1990), Stuart Baker (1926, 1935), Vaurie (1951a, 1959, 1972), Whistler (1932).

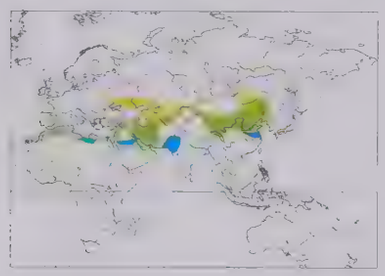
74. Somali Short-toed Lark

Calandrella somalica

French: Alouette roussâtre **German**: Somalilerche **Spanish**: Terrera Somalí
Other common names: Rufous Short-toed Lark; Athi Lark/Short-toed Lark (*athensis*)

Taxonomy. *Alaudula somalica* Sharpe, 1895, Haud, north Somalia.
May form a superspecies with *C. rufescens*, with which sometimes treated as conspecific, and *C. raytal*. Distinctive race *athensis* sometimes considered a separate species. Described race *vulpecula* (from N Somalia) considered synonymous with nominate. Birds recorded in C Kenya of uncertain racial identity, tentatively included in *megaensis*. Four subspecies recognized.
Subspecies and Distribution.
C. s. perconfusa C. M. N. White, 1960 - NW Somalia.
C. s. somalica (Sharpe, 1895) - E Ethiopia and N Somalia.
C. s. megaensis Benson, 1946 - S Ethiopia and N & C Kenya.
C. s. athensis (Sharpe, 1900) - S Kenya (S from Nairobi National Park and Athi Plains) and N Tanzania.

Descriptive notes. 13-14 cm. Heavily streaked, medium-small lark with prominent buffy supercilium, pale lores and crescent under eye, giving "spectacled" appearance, contrasting with darker ear-coverts and moustachial stripe. Nominate race has crown and upperparts bright rufous, heavily streaked dark (especially crown, mantle and back); wings and tail dark brown, wing-coverts and tertials with broad reddish margins, remiges and rectrices with rufous outer webs, outer rectrices with buff outer webs; underparts washed bright pinkish-buff, especially on flanks, breast with well-defined blackish streaks, streaks sometimes coalescing at side of breast to form small dark pectoral patch; eyes dark brown; bill brown above, pale below; legs pale flesh or greyish-white. Sexes alike. Juvenile undescribed. Race *perconfusa* differs from nominate in being less bright above, edgings pale sandy to reddish-buff, whitish below, flanks variably buff, bill pinkish-horn with slightly paler base; *megaensis* is more heavily streaked above than previous, edgings reddish-brown, breast and flanks washed warm brownish; *athensis* is duller, cold grey-brown with broad dark streaks above, white below, breast and flanks washed pale brown. Voice. Song, usually in high flight, also from ground, a protracted series of trills and whistles with some mimicry, similar to that of *Alauda arvensis*; N races (nominate, *perconfusa*) include more scratchy elements as well as distinct clear notes, similar to *C. brachydactyla* and *C. rufescens* but with more distinct notes. Typical call a soft, low "trrrt", in flight or when flushed, combined calls of individuals in flocks producing soft chittering.
Habitat. Dry open grassland, at 600-1600 m in Somalia and 1200-1800 m in Kenya and N Tanzania; prefers areas with slightly taller tussock grasses that provide some cover. More rufous-coloured nominate race occurs on red sands in N Somalia.
Food and Feeding. Diet unknown. Forages on the ground, often in large flocks outside breeding season.
Breeding. Jun in Somalia and Apr-Jun in Kenya and Tanzania. Monogamous; nests singly. Male advertises and defends territory by means of aerial displays. Nest is an open cup of dry grass, built in a shallow scrape in the ground, usually at the base of a grass tuft. Clutch 4-5 eggs in N (nominate), 2-3 eggs in S (*athensis*); nothing known about parental duties or incubation and fledging periods.
Movements. Resident; locally nomadic, moving short distances to follow rain events.
Status and Conservation. Not globally threatened. Common to locally common; often in large flocks when not breeding, although no details on exact numbers. Range of *athensis* has contracted in S Kenya; formerly occurred farther N, to Naivasha region and plains at foot of Mt Kenya; in Tanzania, present in Serengeti and Arusha National Parks.
Bibliography. Archer & Godman (1937-1961), Ash & Miskell (1998), Bennun & Njoroge (1999), Demey (2004b), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960), Short *et al.* (1990), Sinclair & Ryan (2003), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).



75. Lesser Short-toed Lark

Calandrella rufescens

French: Alouette pispolette **German**: Stummellerche **Spanish**: Terrera Marismeña
Other common names: Common/Rufous Short-toed Lark/Sand Lark; Asian/Eastern/Mongolian Short-toed/Grey Short-toed Lark, Lesser Sand Lark (E races)

Taxonomy. *A[lauda] rufescens* Vieillot, 1820, Tenerife, Canary Islands.
May form a superspecies with *C. somalica*, until recently considered conspecific, and *C. raytal*; has sometimes been considered conspecific also with latter, but considerable differences in morphology, song and habitat choice. Was in the past sometimes referred to as *C. pispoletta*; that name has priority, but uncertain whether it applies to present species or to another member of the group. Geographical variation marked and complex; E races often treated as a separate species "*C. cheleensis*", largely on grounds of apparent overlap of races *heinei* and *leucophaea* in region from Turkmenistan to S Kazakhstan, but not clear which taxa should be included within it, usually those E from Turkmenistan, although some authors have included races from as far W as Ukraine (*heinei*) and C Turkey (*niethammeri*); further study needed. Race *tangutica* sometimes merged with *kukunoorensis*, and *stegmanni* with *beicki*. Birds from Transbaikalia named as race *obscura*, but indistinguishable from *cheleensis*; others from Tuva Republic and NW Mongolia described as *tuvinica*, synonymized with *seebohmi* but possibly a valid race; *aharonii* (described from wintering specimens in C Syria) is probably a synonym of *persica*. Sixteen subspecies currently recognized.
Subspecies and Distribution.
C. r. rufescens (Vieillot, 1820) - Tenerife, in WC Canary Is.
C. r. polatzeki Hartert, 1904 - E Canary Is (Gran Canaria, Fuerteventura, Lanzarote).

C. r. apetzii (A. E. Brehm, 1857) - S Portugal and S & E Spain.
C. r. minor (Cabanis, 1851) - N Africa (from S Morocco E to NW Egypt) and from S Turkey S to N Sinai Peninsula and E to C Iraq.
C. r. nicolli Hartert, 1909 - Nile Delta (N Egypt).
C. r. heinei (Homeyer, 1873) - breeds Ukraine E to E Kazakhstan (Semipalatinsk region), S to Aral Sea and Syr Darya Valley.
C. r. leucophaea Severtsov, 1873 - breeds Turkmenistan, Uzbekistan (S of Kyzyl Kum) and SE Kazakhstan E to L Balkhash and Fergana Basin.
C. r. niethammeri Kumerloeve, 1963 - C Turkey (Anatolian High Plateau).
C. r. pseudobaetica Stegmann, 1932 - E Turkey, Armenia, Azerbaijan and NW Iran.
C. r. persica (Sharpe, 1890) - E & S Iraq, Iran (except NW) and W & SW Afghanistan.
C. r. seebohmi (Sharpe, 1890) - S Russia (Tuva), W Mongolia and extreme NW China (Xinjiang, from Tien Shan S to Kashgaria, E to R Khostan).
C. r. beicki Meise, 1933 - SW Mongolia and bordering areas of N China (Gansu, Ningxia).
C. r. stegmanni Meise, 1937 - NC China (NW Gansu).
C. r. kukunoorensis (Przevalski, 1876) - WC China (Qaidam Basin, in N Qinghai).
C. r. tangutica Hartert & Steinbacher, 1933 - S Qinghai and NE Tibet.
C. r. cheleensis (Swinhoe, 1871) - Transbaikalia, NE Mongolia and NE China (S Heilongjiang and Inner Mongolia S to S Shaanxi and N Jiangsu).

Descriptive notes. 13-14 cm; c. 20-27 g. Short-billed, small, heavily streaked lark with whitish narrow supercilium and wide eyering, short, thick-based bill, shortish broad-based wings with relatively long primary projection (tertials end c. 10-15 mm short of wingtips), reduced narrow outer primary (7-12 mm short of primary-covert tips), rather short tail; hind claw short (6-10 mm). Nominate race is distinctive, deep rufous brown above, crown (erectile) with prominent fine blackish streaks, upperparts with broader dark streaks, rump paler with fewer or no streaks; dark-centred median wing-coverts contrast somewhat with rest of upperwing; white outer web of outer rectrix; white below, breast and sides washed light cinnamon-rufous, chest finely and densely streaked dark, streaks usually extending to flanks; bill horn-grey, darker on culmen, base of lower mandible yellowish; legs brownish-flesh to yellowish-brown. Sexes similar. Juvenile has some spotting on upperparts, longer outer primary (with rounded, not pointed, tip) reaching more or less tips of primary coverts. Races vary considerably, mainly in ground colour, width of streaking, amount of streaking on chest and flanks (also in size of wing and tail, and length and shape of bill), and following details only a general guide chiefly to fresh-plumaged birds: *polatzeki* is less rufous than nominate, more sandy brown, with finer streaks above and below; *apetzii* is greyer or buffish-brown with very heavy streaking, more strongly and extensively streaked below; *minor* is buffish sandy to brownish, streaks small; *nicolli* has more warm brown crown and upperparts, broadly streaked, flanks usually unstreaked; *heinei* is paler, grey-brown with well-defined moderate streaking, whiter ground colour below; *niethammeri* is slightly paler and greyer than previous, contrasting black streaks above, chest with thin short black streaks; *pseudobaetica* has heavily streaked rather dark grey-brown upperparts, relatively small size; *persica* is larger and heavier-billed, pale sandy grey above, tinged cinnamon, with narrow streaks, more sparsely streaked below; *leucophaea* is very pale and plain, greyish-white above (looking almost unstreaked in fresh plumage), fewer streaks below, has bolder and whiter supercilium, more white in tail; *seebohmi* is similar to previous, but more sandy and yellowish; *kukunoorensis* is darker and browner than last, more heavily streaked above and below; *tangutica* closely resembles previous, streaks perhaps blacker; *beicki* is more rufous above than previous, breast spotting less distinct; *stegmanni* is like last, but apparently somewhat longer-winged, plumage perhaps very marginally paler and greyer; *cheleensis* is dark brown, darker and less rufous than last two. Voice. Song, mostly in flight, sometimes from ground or low perch, varied and vivacious, a continuous melodious mix of rattles, churrs, trills and whistles with squeaking sounds and buzzy and grating notes, often interspersed with excellent imitations of other bird species, and with only brief and irregular pauses; very different from that of *C. brachydactyla* (which it also mimics). Commonest call a long, dry, buzzing "prrrit" or "chirrick".

Habitat. Open land with shrubs and grasses, and with high percentage of bare ground. Usually in level terrain, but also on slopes; on lime, clay, gypsum or saline soils, also on stony ground in N Africa. In Mediterranean Basin, selects areas with average shrub height 50 cm and bare ground c. 60%; often in saltmarshes with glasswort (*Salicornia*), which apparently preferred in winter. In Turkey and S & E of range found in steppe-like landscapes and semi-deserts, also dry plains and saltflats. Non-breeding visitors in N Indian Subcontinent recorded in sandy semi-deserts and stony foothills. Mostly at low or medium altitudes, to 800 m in Spain; to at least 2000 m in Turkey and to 3000 m in Transcaucasia (*pseudobaetica*). Compared with *C. brachydactyla*, prefers hotter areas and saline or gypsum substrates.

Food and Feeding. Invertebrates and seeds; fruits and bulbs also taken. Diet varies seasonally, mainly invertebrates in spring, mixed in summer, and predominantly seeds in winter. Items taken seem related to abundance of different taxa, with mainly caterpillars in spring and grasshoppers (Acrididae) in summer, although variations occur from one year to another. Nestlings in Spain fed only with insects, mainly grasshoppers, heteropteran bugs, caterpillars and beetle (Coleoptera) larvae, length 6-12 mm. Feeds on the ground, in small parties or larger flocks. Searches ground for food items.

Breeding. Laying from mid-Mar in Canary Is and Israel; elsewhere Apr-Jul, mainly May-Jun; often two broods, sometimes three. Probably monogamous; some pair-members show fidelity during successive clutches, but extra-pair paternity also recorded. Nests singly, sometimes in loose groups with inter-nest distance 100 m or less; territorial. Male song flight, at heights of c. 20-30 m (Canary Is), sometimes higher, in wide circles and with changes of speed, but usually without undulations. Nest built by female, a small scrape on ground beside small shrub or tuft, or in open, lined with vegetation, internal diameter 5-6 cm; earliest nests in season have small rampart of sticks; main orientation in Spain to NE-NW quarter. Clutch 2-6 eggs, usually 3-4 (mode 3); clutch size increases through season in Spain; incubation by female, sometimes assisted by male, begins with last egg, period 13-14 days; chicks cared for and fed by both sexes, nestling period 9 days, sometimes longer, to 12 days, fledging up to c. 15 days. Nest losses often high, as much as 80-90%; possible interspecific nest parasitism by *C. brachydactyla* and *Eremophila bilopha* recorded. Longevity at least 5 years.

Movements. W populations resident, and sedentary or wandering in small flocks, but in N Africa larger movements reported. C & E populations migratory, partly migratory or sedentary; those from N parts of range winter S to Middle East, NW Indian Subcontinent and C & E China. Considerable annual variation in numbers of migrants reported, apparently at least partly dependent on amount of precipitation in region; in Israel flocks generally of up to 500 (exceptionally 1500) in autumn and fewer in spring, but occasional irruptions recorded, e.g. at least 2500 in Arava Desert in spring 1989. Vagrants recorded N to C Europe (several countries), Britain and Fennoscandia, also on Mediterranean islands (Balearics, Sicily, Malta, Crete), in Bulgaria, Romania and, in far E, Japan.

Status and Conservation. Not globally threatened. Rather common throughout very extensive range; locally scarce, but in some places abundant. Often localized, but attaining high densities in favourable habitats, e.g. 1-3 birds/ha in Spain. In W, common and widespread in E Canary Is, where estimated 17,000-19,000 pairs (mostly on Lanzarote and Fuerteventura); widespread over much of steppe country of C Morocco and Hauts Plateaux, N to coast; more rare and local than *C. brachydactyla* in Algeria, occurring in large flocks at Constantine Plateau; common in Tunisia (mainly coastal areas); in Egypt, fairly common in Nile Delta saltmarshes. Highly disjunct distribution in Europe, with estimated 230,000-260,000 pairs in Spain (most in Ebro Valley and littorals of SW & SE), a few pairs on S coast of Portugal, c. 10,000-17,000 pairs in Ukraine, and perhaps more than 300,000 pairs in Russia; locally common to very common in Turkey (10,000-100,000 pairs), common to very common in Azerbaijan. Common in Israel and in Jordan (most abundant lark at Azraq); breeds in small numbers in Saudi Arabia when conditions favourable, not in every year (although probably most numerous breeding bird at Harrat Al Harrah Reserve); may breed locally in Qatar. Common, in places numerous, in Asia within former URSS; fairly common in China. Possibly breeds in W Pakistan. Decreases reported in Iberia, where species is locally regarded as "near-threatened" (race *apetzii*), and in Canary Is, where considered "endangered" on Gran Canaria (*polatzeki*) and "critical" on Tenerife (nominate); threatened by habitat loss brought about by agriculture and touristic developments, also locally by excessive predation, e.g. on Tenerife by introduced predators including rats (*Rattus*), cats and hedgehogs (*Erinaceus*).

76. Sand Lark

Calandrella raytal

French: Alouette raytal **German**: Uferlerche **Spanish**: Terrera Raytal
Other common names: Asian/Indian Short-toed Lark, Indian Sand Lark, Raytal Lark

Taxonomy. *Alauda raytal* Blyth, 1845, Lucknow, India.
May form a superspecies with *C. somalica* and *C. rufescens*; has been treated as a race of latter, but differs in morphology, song and habitat choice. Named race *vauriei*, known only from type locality in NE India (Palasbari, in Assam), synonymized with nominate. Race *adamsi* intergrades with nominate in N India (Haryana). Three subspecies recognized.

Subspecies and Distribution.
C. r. adamsi (Hume, 1871) - SE Iran, Pakistan and NW India (Punjab, Haryana, NW Gujarat).
C. r. raytal (Blyth, 1845) - N India (E from Haryana to Arunachal Pradesh), Nepal, Bangladesh and C & S Myanmar.
C. r. krishnakumarsinhji Vaurie & Dharmakumarsinhji, 1954 - Bhavnagar, in S Gujarat (W India).

Descriptive notes. 12-13 cm. Small, pale lark with comparatively long, slender bill, relatively short tail, distinct primary projection. Nominate race has pale greyish-white supercilium; crown and upperparts pale brownish-grey with faint thin dark streaks, upperwing-coverts and tertials medium grey-brown with pale buffish or buffish-white tips and edges; remiges dark grey-brown; tail feathers dark grey-brown, central pair with narrow greyish edges, outermost pair with large white wedge on inner web; whitish below, fine dark streaks across breast; bill pale greenish or pale brownish-yellow, darker culmen; legs pinkish. Differs from *C. rufescens* (mainly races *persica* and *leucophaea*) in smaller size, proportionately longer and slimmer bill and shorter tail, less distinctly streaked upperparts. Sexes similar in plumage, female on average smaller than male. Juvenile has whitish fringes and indistinct dark subterminal bands above. Race *adamsi* resembles nominate, but bill shorter and slightly thicker; *krishnakumarsinhji* has bill like previous but is darker and more heavily streaked above. Voice. Song, mainly in high flight, rather short (usually 2-4 seconds), dry, rattling, slightly "undulating" strophes interspersed with fairly long (often 10 seconds or more) pauses, resembles that of *C. rufescens* but slightly less varied; when on ground, and in low flight (or during ascent to high song flight), sings with continuous flow of call notes (both dry rattling and whistled), single elements or complete strophes of the first song type and some mimicry, resembles corresponding song type of *C. rufescens* (of race *cheleensis*) but less varied. Call a low-pitched rolling "chirr", "cherr", "chirr-de" or similar, like calls of *C. rufescens*.

Habitat. Mainly dry, sandy riverbanks and islands in rivers. Race *adamsi* also occurs in sandy areas along coast and on dry margins of some large lakes (the only habitat where *krishnakumarsinhji* has been found).

Food and Feeding. Food poorly known. Small snails (of genera *Planorbis* and *Corbicula*), other invertebrates; also seeds, especially of *Salsola* and *Suaeda* and other Chenopodiaceae (which predominate in preferred habitat). Forages on the ground.

Breeding. In nominate race, season Feb-May, chiefly Mar and Apr; *adamsi* apparently breeds from mid-Mar to mid-May and, after good monsoons, also in Aug and Sept (thus probably attempting two broods). In high song flight, male hangs more or less still or drifts about, alternating between a few wingbeats and short glides; in low song flight (as well as during ascent to high one), flies about in irregular "circles" with characteristically slow, deep, "rowing" wingbeats and partly fanned tail, in similar form to corresponding song flight of *C. rufescens*. Nest, built by both sexes, a cup-like depression in the ground, often sheltered by small bush, stone or tuft of grass, lined with animal hairs and fine vegetable matter. Clutch usually 3 eggs, sometimes 2; both sexes participate in tasks of incubation and chick-feeding; incubation and nestling periods not documented.

Movements. Resident.

Status and Conservation. Not globally threatened. Locally common; no estimates of population size. Common in Pakistan, locally common in N India and Nepal, and fairly common but very local in Bhutan; local in Bangladesh; common in C & S Myanmar. Race *krishnakumarsinhji* recorded only at type locality in Gujarat (India), possibly vulnerable to habitat deterioration.

77. Horned Lark

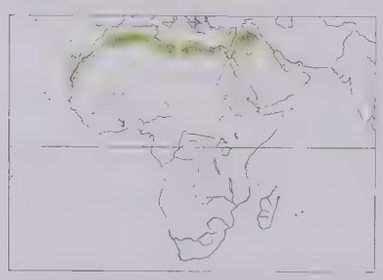
Eremophila alpestris

French: Alouette hausse-col **German**: Ohrenlerche **Spanish**: Alondra Cornuda
Other common names: Shore Lark; Przewalski's Lark (*teleschowi*)

Taxonomy. *Alauda alpestris* Linnaeus, 1758, coast of South Carolina, USA.
Genus distinct in plumage and structure, particularly bill structure; probably closest, although still distantly related, to *Alauda* and *Galerida*. Forms a superspecies with *E. bilopha*, formerly considered conspecific. Highly variable over vast range, and numerous races described, broadly separable into two main types: all New World races together with Old World *flava*, *brandti* and *atlas* (having black face mask not connected to black breastband), and remaining Old World races (mask usually joining with breastband). Races described mainly on basis of differences in size and in plumage ground colour (at least partly determined by local soil colour) and pattern, but many grade into each other, with many intermediates, and variation thus possibly clinal; some named taxa perhaps not sustainable, but all are listed, with breeding ranges, for sake of completeness; thorough review needed. Race *teleschowi* sometimes treated as separate species, apparently not interbreeding with other races where ranges overlap. Forty-two subspecies currently recognized.
Subspecies and Distribution.
E. a. arcticola (Oberholser, 1902) - Alaska and NW Canada (Yukon S to British Columbia).
E. a. hoyti (Bishop, 1896) - N Canada (N Baffin I S to N Alberta and W Ontario).
E. a. alpestris (Linnaeus, 1758) - E Canada (W Ontario E to Newfoundland).
E. a. merrilli (Dwight, 1890) - W coast of Canada and USA (British Columbia S to N California).
E. a. strigata (Henshaw, 1884) - coastal S British Colombia and NW USA (S to Oregon).
E. a. alpina (Jewett, 1943) - extreme NW USA (Olympic Mts and Cascade Range, in W Washington).
E. a. lamprochroma (Oberholser, 1932) - inland montane W USA (Washington S to N California and E to Nevada).
E. a. leucolaema Coues, 1874 - SW Canada (S Alberta) S to WC USA (S to Colorado and New Mexico).
E. a. enthymia (Oberholser, 1902) - Great Plains from SC Canada (Saskatchewan, Manitoba) S in USA to Oklahoma and Texas.
E. a. praticola (Henshaw, 1884) - E USA (from Minnesota) E to SE Canada (E to Nova Scotia), S to Kansas and N Carolina.
E. a. sierrae (Oberholser, 1920) - mountains of NE California.
E. a. rubea (Henshaw, 1884) - C California.
E. a. utahensis (Behle, 1938) - montane WC USA (Idaho S to C Nevada and Utah).
E. a. insularis (Dwight, 1890) - Channel Is, off SW California.
E. a. actia (Oberholser, 1902) - Coast Ranges of S California and extreme NW Mexico (N Baja California).
E. a. ammophila (Oberholser, 1902) - Mojave and Amargosa Deserts, in SE California and adjacent SW Nevada.
E. a. leucansiptila (Oberholser, 1902) - Colorado Desert from SW Nevada and W Arizona S to extreme NW Mexico (NE Baja California, NW Sonora).
E. a. occidentalis (McCall, 1851) - N Arizona E to C New Mexico.
E. a. adusta (Dwight, 1890) - S Arizona E to S New Mexico.
E. a. enertera (Oberholser, 1907) - C Baja California.
E. a. giraudi (Henshaw, 1884) - coastal S USA (S Texas) S to NE Mexico.
E. a. aphrasta (Oberholser, 1902) - NW Mexico (S to Durango).
E. a. lactea A. R. Phillips, 1970 - NE Mexico (Coahuila).
E. a. diaphora (Oberholser, 1902) - extreme SE Coahuila S to NE Puebla.
E. a. chrysolaema (Wagler, 1831) - S Mexican Plateau from Zacatecas S to Jalisco, Michoacan, Morelos and Veracruz.
E. a. oaxacae (Nelson, 1897) - S Mexico (E Oaxaca).
E. a. peregrina (P. L. Sclater, 1855) - E Andes of Colombia (Altiplano Cundiboyacense, N of Bogotá).
E. a. flava (J. F. Gmelin, 1789) - N Eurasia E to NE Russia (Anadyrland), S to S Norway, L Baikal and NW Amurland.
E. a. brandti (Dresser, 1874) - SE European Russia (lower R Volga) and N Transcaspia E to W Manchuria, S to N Turkmenistan, Tien Shan and Mongolia.
E. a. atlas (Whitaker, 1898) - Morocco (Atlas Mts).
E. a. balcanica (Reichenow, 1895) - SE Europe (S Balkans and Greece).
E. a. kumerloevei Roselaar, 1995 - W & C Asia Minor.
E. a. penicillata (Gould, 1838) - E Turkey and Caucasus E to N & W Iran.
E. a. bicornis (C. L. Brehm, 1842) - Lebanon and N Israel-S Syria border (Mt Hermon).
E. a. albigula (Bonaparte, 1850) - SW Turkmenistan and NE Iran E to W Tien Shan and S to NW Pakistan.
E. a. argalea (Oberholser, 1902) - N Ladakh, extreme W China (W Kun Lun Mts) and W Tibetan Plateau.
E. a. teleschowi (Przevalski, 1887) - C & E Kun Lun Mts from S Xinjiang E to NW Qinghai and S to N Xizang (W China).
E. a. przewalskii (Bianchi, 1904) - Qaidam Basin, in N Qinghai.
E. a. nigrifrons (Przevalski, 1876) - mountains of NE Qinghai.
E. a. longirostris (F. Moore, 1856) - Himalayas from NE Pakistan and Kashmir E to Sikkim.
E. a. elwesi (Blanford, 1872) - S & E Tibetan Plateau.
E. a. khamensis (Bianchi, 1904) - SC China (SE Xizang, W Sichuan).
Descriptive notes. 14-17 cm; 30-40 g. Medium-sized lark with short bill, fairly long tail, and striking head pattern with elongated lateral crown feathers ("horns"). Male nominate race has yellow forehead and supercilium, yellow from chin and throat extending across lower neck side to meet yellowish ear-coverts (latter darker and browner at rear), all contrasting with blackish central crown with elongated lateral feathers, blackish lores and broad band from eye down to cheek, and black chestband; central crown to upper mantle, also rump and uppertail-coverts, warm rufous-brown

with pinkish tinge, rest of upperparts greyer and dark-streaked, wings somewhat darker with pale edgings; tail blackish, central feathers paler and greyish, outer feathers edged white; underparts below chestband whitish, breast side to rear flank washed pinkish-rufous, breast streaked; bill dark grey to black; legs black. Non-breeding male has head pattern partly obscured (pale fringes), "horns" often shorter (often invisible in field). Female resembles male but smaller, slightly duller, with black bands on head and chest a little narrower. Juvenile has head and upperparts heavily mottled blackish and white, throat and lower neck side creamy whitish, chestband mottled; after autumn moult resembles adult. Races differ mostly in plumage colour and pattern, mainly of males, also in size (migratory races larger, darker and relatively longer-winged than resident ones, those in mesic habitats tend to be larger than those in arid habitats, and size also decreases with altitude): in N America, arctic races (e.g. *arcticola*) are somewhat darker and slightly less streaked above than nominate, nape pinkish, pale areas of face whitish (not yellow), W races (e.g. *merrilli*, *strigata*, *rubea*) have dark reddish nape to upper mantle and breast side, heavily streaked upperparts and bright yellow on head, those in interior W (e.g. *utahensis*) are paler and greyer with less streaking, palest and unstreaked in S deserts (*adusta*), greyer and streaked in S Texas (*giraudi*); Neotropical *peregrina* has forehead and supercilium whitish, throat yellow, nape greyish, upperparts dark grey with contrasting pinkish lesser and median coverts; in Eurasia, *flava* is very like American nominate (but with lesser coverts paler, less deep red), *atlas* is similar but paler, *brandti* is also similar but has pale areas on head whitish (not yellow); in most of remaining Old World races black of cheekband meets (or more or less meets) black of chestband, *balcanica* has yellow on face and throat, dark-streaked grey upperparts, *penicillata* has paler yellowish-white on head, pink hindneck, pink-tinged greyish-buff upperparts with fine streaks on mantle and scapulars, *kumerloevi* resembles previous but with unstreaked greyish-pink upperparts, *bicornis* has pale areas on head even whiter, crown to rump uniform plain sandy buff, tail-coverts tinged cinnamon, other E races generally rather pale, greyish to sandy, e.g. *albigula* has pale parts of head white, grey central crown and hindneck, finely streaked sandy grey upperparts, *longirostris* is slightly darker than previous, with black of cheekband and chest separated by white lower neck side, *teleschowi* is pale with black (not white or yellow) forehead. Voice. Song, from ground or in air, often consists of a few simple, rippling trills followed by short chatter, less fluent than that of many other larks; a second song is more like that of *Alauda arvensis* but less ebullient and less loud. Usual flight call "eeh" or "ééh-ti", or liquid "tur-reep"; occasional harsh "tsrr".
Habitat. The only lark to have successfully colonized tundra and alpine habitats; throughout range prefers mainly barren terrain with very short vegetation. In North America, where the only breeding representative of the family, widely distributed across most open habitats, occurring from sea-level to c. 4000 m and from tundra and mountains to steppe, desert and other bare ground, also wide variety of farmland types; shows a preference for recently burned sites; will also feed on sandy beaches and breed in sand dunes; highest densities occur where bare ground predominates, and in grassland and other grazed habitats most numerous in more heavily grazed areas. In Andes, race *peregrina* found in short-grass pastureland and bare fields, to at least 3100 m, probably higher. In Eurasia, breeds mainly in arctic tundra, dry stony patches in lichen tundra, barren steppes and arctic-alpine zones; breeds up to snow-line, to 5400 m in Himalayas. Also on open coasts and dunes in non-breeding season; in W Europe, migrants of race *flava* largely confined to open coastal habitats around North Sea in winter.
Food and Feeding. Wide range of invertebrates in summer and plant material in winter. Main invertebrate prey items are grasshoppers (Acrididae), beetles (Coleoptera), flies (Diptera) and lepidopteran larvae; nestlings fed almost entirely with these invertebrates, also with earthworms (Annelida). Seeds, especially small grass seeds, particularly important in winter, when may comprise entire diet; flocks wintering around North Sea coasts (W Europe) feed largely on energy-rich halophyte seeds found in lower saltmarshes. Forages on ground, singly or in small to large, tightly knit flocks; walks and runs. Obtains most food items directly from soil surface; occasionally digs, pursues flushed prey by running, and takes seeds directly from plants. Occasionally drinks water around dawn.
Breeding. In North America, season from mid-Feb in S USA (one of earliest nesters) and from mid-May in Canadian Arctic; in Eurasia, breeds from late May to mid-Jul in Scandinavia but from mid-Jun in arctic Russia; one brood in N of range, 2-3 broods in S. Apparently monogamous; territorial, breeding territory 0·3-5·1 ha depending on habitat. Song-flighting male ascends to great height, up to 250 m, hovers while singing, drops vertically back to earth; generally less aerial than many other larks. Nest, built by female alone, an excavated cavity or natural depression on ground, filled with woven plant material, lined with feathers or other fine material, with stones, bark, clods of earth, animal dung and other material placed around it; nest usually positioned in such a way as to reduce wind flow across it to as little as a tenth of ambient wind speed and to maximize shade. Clutch 1-8 eggs, mostly 2-5, clutch size increasing with increasing latitude; incubation by female alone, period 11-12 days; chicks fed by both parents, leave nest at c. 9-12 days, fly at 16-18 days, reach full adult size at c. 30 days. Success variable; at high altitudes in Asia, productivity in some years reduced to zero by severe cold; drought may also reduce productivity of populations at lower latitudes; nests often parasitized by Brown-headed Cowbird (*Molothrus ater*) in North America. Recorded longevity at least 8 years.
Movements. Migratory or partially migratory in N; mostly resident or altitudinal migrant in S. Across Holarctic Region, races in far N wholly migratory, with much or all of breeding range abandoned in winter (usually by late Oct, earlier in Russia): *arcticola* and *hoyti* migrate to W & N USA, nominate to SE USA, and *flava* to coasts of W Europe (S North Sea, W Baltic Sea), less regularly inland in C & E Europe, and in large numbers across C Asia (S to Sea of Azov, N Caucasus, N Kazakhstan and NE China); returning birds arrive as early as late Feb in S Canada, but not until Apr or early May in Alaska and N Canada, and in Eurasia from late Apr in W (N Norway) and from mid-May in extreme N Russia; males arrive back on breeding grounds before females. Several races are partial or altitudinal migrants in N of respective ranges, e.g. *strigata*, *praticola*, *enthymia* and *leucolaema* from S Canada move S after breeding, some reaching N Mexico, and those breeding in high mountains of Asia (e.g. *albigula*, *longirostris*) descend to lower elevations in winter. In addition, some populations of S USA deserts (*ammophila*, *occidentalis*) undertake short-distance movements to NW & N Mexico. Generally in flocks, usually of up to 50 individuals

On following pages: 78. Temminck's Lark (*Eremophila bilopha*); 79. Dunn's Lark (*Eremalauda dunni*); 80. Stark's Lark (*Spizocorys starki*); 81. Pink-billed Lark (*Spizocorys conirostris*); 82. Botha's Lark (*Spizocorys fringillaris*); 83. Obbia Lark (*Spizocorys obbiensis*); 84. Masked Lark (*Spizocorys personata*); 85. Sclater's Lark (*Spizocorys sclateri*); 86. Short-tailed Lark (*Pseudalaemon fremantlii*).



but sometimes to several hundred in hard weather, during migration and outside breeding season. Nominate race recorded as vagrant in UK and Bermuda; *flava* recorded annually in Japan.
Status and Conservation. Not globally threatened. Common to locally very common; scarce in some areas. Has one of the largest world ranges of any songbird, and is the only alaudid occurring naturally in the New World (apart from *Alauda arvensis*, which has recently gained a tenuous foothold in W Alaska). Across much of range, and particularly in North America and arctic Eurasia, one of the commonest bird species in a wide range of open habitats; spread of cultivation led to considerable range expansion in North America at end of 19th century and beginning of 20th century. Global population almost certainly very large, but few reliable data; estimates at end of 1990s include c. 6370-18,560 pairs in Europe (most in Norway), 10,000-100,000 pairs in Turkey and 100,000-1,000,000 pairs in Russia; fairly common in SE Europe, and density in Caucasus up to 4·5-6 birds/km²; locally common in Middle East and N Africa, and common in China. No figures for North America but widespread and common, probably several million pairs; fairly common to common in Mexico. Race *peregrina*, restricted to Altiplano Cundiboyacense, in Colombian Andes, is rare, and declining rapidly as a result mainly of spread of introduced Kenyan kikuyu grass (*Pennisetum clandestinum*), unfavourable agricultural practices and unrestricted use of pesticides; in 2002 total of 401 individuals located, and population estimated at fewer than 1000. Some North American races also have small ranges and populations, although trends across the continent appear stable. Declining in some areas, largely because of changes in agriculture; replacement of arable crops by biomass-fuel production, and of conventional tillage by minimum tillage, poses threats in some parts of North America, as does agricultural abandonment; direct poisoning by pesticides has also been recorded, and this species may be particularly susceptible to this risk as in some areas it is a significant pest of crops, and chemical repellents are used to reduce crop damage. Other populations are increasing; for example, deforestation for farmland or airstrips has allowed the species to colonize formerly forested regions across much of North America. In Europe, drastic declines noted since 1950s in N Fennoscandia, especially Finland, believed possibly due to overgrazing of lichen by reindeer (*Rangifer tarandus*), but increase and range extension recorded in Balkans; expansion in area of coastal marshes in Netherlands as a result of improved flood defences led to increase in numbers of this species wintering there.

(1998a, 2003b), Apa *et al.* (1991), Ballman (1972), Beason (1970, 1984, 1995), Beason & Franks (1973, 1974), Behle (1942), Bent (1942), Bock & Bock (1992), Bock & Webb (1984), Boutin *et al.* (1999), Boyd (1976), Brazil (1991), Brazil & Cook (1991), Brodkorb (1978), Brown & Atkinson (1996), Brugiere (1988), Cadena (2002b), Campbell, Dawe *et al.* (1997), Cannings (1981), Cannings & Threlfall (1981), Castralle (1982, 1983), Chandler & Martin (1988), Clark & Karr (1979), Cramp (1988), Crutchfield (1985), DeGraaf & Rappole (1995), Dementiev *et al.* (1970), Deng Heli & Zhang Xiaoai (1991), Deng Heli *et al.* (1991b), Dickerman (1964), Dickinson & Dekker (2001a), Dierschke (2001, 2002a, 2002b), Dierschke & Bairlein (2002), Drury (1961), DuBois (1935, 1936), Dwight (1890), Ehrich (1997), Emslie (1985), Garner (1999), George *et al.* (1992), Godlinsky (1996a), Gorski (1982), Grimmett *et al.* (1998), Grzybowski (1976, 1983a, 1983b), Hagemeijer & Blair (1997), Hartman & Oring (2003), Heath *et al.* (2000), Heim de Balsac (1936), Hellmayr (1935), Hildén (1987), Hilty & Brown (1986), Hofer (1983), Howell & Webb (1995a), Hsu Weishu (1988), Hüe & Étchécopar (1970), Hurley & Franks (1976), Igl & Johnson (1997), Ilani & Shalmon (1984), Inskipp & Inskipp (1991), Kaufman (1996), Klimkiewicz & Futcher (1989), Lobachev & Kapitonov (1968), Mackinnon *et al.* (2003), Maher (1979, 1980), Martin & Forsyth (2003), McAtee (1905), McNicholl (1988), Meinertzhagen (1954b), Michelat (1998), Mishra (2000), Mousley (1916), Munteanu & Szabó (2001), Murray *et al.* (2003), Nelson & Martin (1999), Niles (1972c, 1973), Norvelle & Creighton (1990), Olafsson (1983), Parmalee & Klippel (1982), Patterson & Best (1996), Pätzold (1979, 1981, 1987, 1991), Peck & James (1987), Petersen & Best (1987), Pickwell (1931), Pittaway (1994), Plucinski (1987a, 1987b), Price *et al.* (1995), Reynolds & Shorey (1984), Ridgely & Tudor (1989), Ripley (1982), Roberts (1992), Root (1988), Rotenberry & Wiens (1976), Rousset (1998), Rust (2003), Ryabitsev & Tyulkin (1985), Sáez-Royuela (1952), Schlogel (1989), Shirihai (1996), Small (2002), Snow & Perrins (1998), Spjøtvoll (1970), Stepanyan (1990), Stotz *et al.* (1996), Sutter *et al.* (2000), Sutton (1927), Sutton & Parmelee (1955), Svensson (1990, 1997), Svensson & Berglund (1995), Svensson *et al.* (1992), Swain (1989, 1991, 1992a, 1992b), Thévenot *et al.* (2003), Thiede (1989), Trilar (1999), Trost (1972), Vaurie (1959), Verbeek (1967), Whistler (1932), Whitmore (1980), Wiens & Rotenberry (1979, 1980, 1985), Wiens *et al.* (1986, 1987), Wing (1946), With & Webb (1993), York *et al.* (2000), Zhao Liang *et al.* (2002), Zheng Shengwu (1984).

78. **Temminck's Lark**

Eremophila bilopha

French: Alouette bilophe **German**: Saharaohrenlerche **Spanish**: Alondra Sahariana
Other common names: Temminck's Horned Lark

Taxonomy. *Alauda bilopha* Temminck, 1823, deserts of Aqaba, north-west Arabia.
Genus distinct in plumage and structure, particularly bill structure; probably closest, although still distantly related, to *Alauda* and *Galerida*. Forms a superspecies with *E. alpestris*, formerly considered conspecific. Smaller birds from S Western Sahara (Río de Oro) described as race *elegans*, but similarly small birds occur elsewhere in species' range (e.g. Libya and W Egypt). Monotypic.
Distribution. Extreme NW Mauritania, Western Sahara and S & E Morocco E to NE Egypt (Sinai Peninsula) and Middle East (Syria, Jordan, S Israel, W Iraq, N Saudi Arabia, Kuwait).

Descriptive notes. 13-15 cm; c. 38-39 g. Small, neat, uniform-looking lark with striking head pattern, rather thin bill, rather short and broad wings with short primary projection, narrow pointed outer primary reduced (9-13 mm short of tips of primary coverts), straight hind claw (5·5-8·2 mm). Male has white face with contrasting black on lower part of forehead, lores and from eye down to cheek, black forecrown with elongated lateral feathers ("horns"), black chestband; central crown to nape and rear ear-coverts sandy rufous, nape often washed pinkish, upperparts sandy rufous with slight mottling (visible at close range), upperwing-coverts and tertials reddish with pale edgings, primary tips contrastingly blackish; tail black, central rectrices rufous, outer ones white; underparts whitish, sides washed rufous-buff; bill greyish; legs flesh-grey to bluish-grey. Female is very like male, but black areas of face and chest slightly less well defined, "horns" shorter. Juvenile is very different, lacks black-and-white pattern on face and chest, has faint white spots on upperparts, longer outer primary (5-6 mm short of primary coverts) is broader with more rounded tip. Voice. Song, in flight or, perhaps more commonly, from ground, a series of soft, usually short, rather monotonous twittering and warbling phrases with short whistles, e.g. "dee dee-eeee" or "chep-chep-chew-eeee", very like that of *E. alpestris* but quieter, less vigorous, with finer notes. Calls include quite loud "tsip" or "sweeep", like that of a wagtail (*Motacilla*).

Habitat. Open flat plains, mainly on fringe of true desert, also in completely barren landscapes; usually on stony or compacted soils, avoiding soft sand. In N Africa occurs in steppe areas and high plateaux with annual rainfall 200-250 mm, mostly with wormwood (*Artemisia*) shrubs or *Stipa* or *Lygeum* grasses, also slopes with low-growing patches of the succulent *Aizoon*. Mainly lowlands, to 1000 m in N Africa.
Food and Feeding. Predominantly seeds; occasionally insects, e.g. beetles (Coleoptera), some fruits; nestling diet not known. In NW Africa seeds, mainly those of *Aizoon* in spring and summer. Forages on ground, in pairs or in small groups; often in loose association with other alaudids. Runs nervously, then slowly, pecking seeds from ground surface; also uses bill to displace and turn over stones, including those heavier than the bird itself.
Breeding. Lays Feb-May, mostly from mid-Apr; apparently single-brooded. Probably monogamous; solitary and territorial, inter-nest distance in S Israel usually large (few hundred metres to several kilometres). Male song flight very brief, rising to c. 20-25 m, hovering while singing, dropping vertically back to ground. Nest a shallow scrape lined with grass, rootlets and small twigs, topped with soft grass-heads, internal diameter 7 cm, on ground in the open or beside a shrub, with rampart of small stones. Clutch 2-4 eggs (mode 3); incubation 13-14 days; chicks cared for and fed by both parents, leave nest at 10-12 days, able to fly a few days later, at 15-16 days. Possible interspecific nest parasitism recorded; a pair observed to feed chicks of *Calandrella rufescens*.
Movements. Resident, with limited dispersive movements. Dispersal somewhat irregular, little known. In N Africa moves short distances in flocks of c. 20 birds, probably more on occasion. Apparently more regular movement in E of range; large winter flocks, sometimes mixed with other larks, observed S of breeding range in Saudi Arabia; mostly a breeding visitor (Feb-Nov) in S Israel, where observations indicate also small seasonal passage movements S in Oct-Nov and, especially, N in Mar-May (usually flocks of up to 40 individuals, highest total 1340 birds during Mar-Apr 1989). Vagrants recorded in Lebanon and S Arabia (Yemen, United Arab Emirates), also in Malta, possibly also Spain (19th-century report); also in Gambia in 2002.
Status and Conservation. Not globally threatened. Common to fairly common in most of range; scarce in some areas. In comparison with other Saharan larks, has fairly continuous distribution but limited to N parts of that region, and not extending far into Asia. In N African range, locally abundant in Western Sahara (Ugranat plains, where up to 560 birds in 21-km vehicle transect) and Morocco (Hauts Plateaux), frequent and widespread in Algeria (50 birds in 16-km transect in Laghuat), and scarce in Tunisia (but frequent Chott Rharsa); widespread in NW Libya (Tripolitania) and fairly common in Egypt (locally common along N coast from border E to Nile Delta, local in Sinai). In Middle East, common in Jordan (third commonest lark in Azraq area, very common at Shaumari) and in W deserts of Iraq; locally common in Tadmur (Palmyra) area of Syria and in C deserts of N Saudi Arabia; scarce and local in Kuwait; local, and scarce to uncommon, in Israel, with possibly no more than a few tens of pairs remaining following marked decline in 1980s, believed due mainly to loss of habitat.

Genus *EREMALAUDA* W. L. Sclater, 1926

79. **Dunn's Lark**

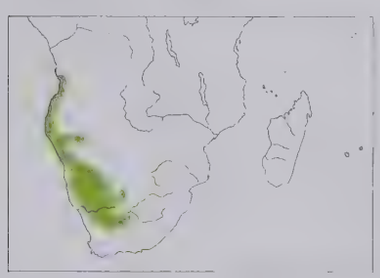
Eremalauda dunni

French: Alouette de Dunn **German**: Einödlerche **Spanish**: Alondra de Dunn

Taxonomy. *Calendula dunni* Shelley, 1904, Ogageh Wells, Kordofan, Sudan.
Sometimes placed in genus *Ammomanes*, and has been considered by some to be close to *Ammomanopsis grayi*, but appears distinct. Two subspecies recognized.
Subspecies and Distribution.
E. d. dunni (Shelley, 1904) - S edge of Sahara in Mauritania, N & C Mali, S Niger, N Chad and C Sudan.
E. d. eremodites (Meinertzhagen, 1923) - Jordan (Azraq), S Israel (sporadic), N & C Saudi Arabia and SW Oman.

Descriptive notes. 14-15 cm. Small but relatively bulky lark with sand-coloured plumage, strong facial pattern, heavy deep-based bill quite large (around half of head length), strongly curved on culmen, broad and rounded wings with long tertials, very short primary projection, reduced outer primary (0-4 mm short of tips of primary coverts), short tail; hind claw short (6·6-8 mm) and curved. Nominate race has broad whitish eyering and short supercilium, latter more evident in front of eye, thin dark moustachial and malar stripes; pinkish-tinged to orange-tinged sandy brown above, crown to mantle lightly streaked red-brown (streaks most distinct when plumage worn), wings rather pale and uniform, blackish tips of outer primaries; tail buff centrally, black sides, outer edge of outer rectrix white (tail pattern striking in flight); whitish below, breast washed sandy, breast side faintly streaked red-brown; bill pale-coloured, pinkish to orange; legs pinkish. Sexes similar. Juvenile has white spots on tips of crown, mantle and scapular feathers, lacks black on tips of primaries, has outer primary longer and with more rounded tip than that of adult. Race *eremodites* is larger and longer-billed than nominate, also less pinkish, with fewer streaks dark brown (less reddish), more obvious black primary tips. Voice. Male song, from ground or low perch, a rapid repetition of chirping and dry notes mixed with whistles, e.g. "wit-wit-wtrrreedritdritdridrree", or in flight and then sometimes more varied and

rattling, scratchy warbling with interposed short whistled phrases. Flight call "ziup", "chiup-chiup", "two-weep"; also thin "prrrp" or "chrruit"; alarm call on rising a loud "chhe-oop" or "chup-chup-chup". Repeated high, plaintive "pee-pee" or "peeuw-peeuw-peeuw" by fledglings.
Habitat. Open arid lowlands, flat or undulating, and with gravel or compacted sandy soils; avoids broken ground, rocky slopes and soft sandy substrates. In deserts, prefers wadis with sparse dry herbaceous cover. Also in flat stony desert in non-breeding season.
Food and Feeding. Few data. Diet mainly small seeds (*Panicum turgidum* and others), but stomach of one individual from Mali contained insects. Chicks fed with caterpillars in Saudi Arabia. Forages on ground, singly or in pairs, also in small flocks outside breeding season. Searches ground surface, alternately running nervously and pausing; also digs for seeds with the bill, and rummages in low vegetation.
Breeding. Poorly known. Season determined by rainfall; nesting recorded in Jan, after rains, in Mauritania; laying in Apr in Israel; single-brooded. Solitary, territorial. Song-flighting male rises to c. 30 m, occasionally 50 m or more, hovers with slow wingbeats, swinging from side to side, slowly parachutes back to ground. Nest a scrape on ground, under or beside a tussock or small shrub, lined with fresh vegetation; roles of sexes in building unknown. Clutch 2-3 eggs; incubation by both sexes, mainly female, period 13-16 days; chicks fed by both sexes, leave nest at c. 10 days, able to fly 3-6 days later.
Movements. Resident; some nomadic movements occur, probably related to drought conditions. Wanders in usually small flocks of up to 20 individuals, sometimes mixed with other alaudids. Periodic irruptions into areas outside normal range; in Nov 1988, following exceptional rainfall in preceding winter, hundreds appeared in desert areas of Arava Valley, on S Israel-Jordan border, some remaining to nest. Accidental in Lebanon, Kuwait, Yemen and United Arab Emirates.
Status and Conservation. Not globally threatened. Status difficult to assess; generally uncommon and irregular in most of fragmented range, but possibly under-recorded owing to identification problems and/or nomadic habits. Reported as widespread but irregular, and common to uncommon, in Mauritania (breeding confirmed at Zemmour in 1970), locally common from Mali E to Chad, and uncommon in Sudan; others report it as uncommon to rare in African range. Presence in S Western Sahara and S Algeria suspected, but not proven. Race *eremodites* common in N Saudi Arabia, but uncommon in other areas of this country, and rather scarce and local in Oman; irregular in Jordan (breeding first confirmed 1965), and sporadic in Israel (first breeding 1989); irregular in NE Egypt (NE Sinai Peninsula), nested in 1990.
Bibliography. Baha-El-Din (1990), Bannerman (1953), Brooks, D.J. *et al.* (1987), Bundy & Warr (1980), Castell *et al.* (2002), Cave & Macdonald (1955), Cowan & Brown (2001), Cramp (1988), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Étchécopar & Hüe (1964), Gallagher & Woodcock (1980), Goodman *et al.* (1989), Harrison (1962), Heard & Kirwan (1997), van Heezik & Seddon (1999), Heim de Balsac & Mayaud (1962), Hollom *et al.* (1988), Isenmann & Moali (2000), Jennings (1980b, 1981, 1995), Keith *et al.* (1992), Lamarche (1981), Ledant *et al.* (1981), Lees-Smith (1986), Lunais (1983), Mackworth-Praed & Grant (1960, 1970), Mayaud (1985), Meinertzhagen (1951, 1954a), de Naurois (1974), Newton & Newton (1997), Niethammer (1963a), Nikolaus (1987), Pilcher *et al.* (1990), Rietkerk & Wacher (1996), Round & Walsh (1981), Shirihai (1991a, 1991b, 1994, 1996), Shirihai *et al.* (1990), Snow & Perrins (1998), Svensson *et al.* (1999), Ter Haar (1981), Tieleman (2002), Tieleman & Williams (2002a), Tieleman, Williams & Buschur (2002), Tieleman, Williams, Buschur & Brown (2003), Vaurie (1959), Walker (1981b), Wallace (1983).



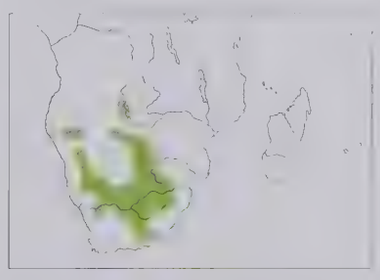
Genus *SPIZOCORYS* Sundevall, 1872

80. Stark's Lark

Spizocorys starki

French: Alouette de Stark **German**: Falblerche **Spanish**: Alondra de Stark
Other common names: Stark's Short-toed Lark

Taxonomy. *Calandrella starki* Shelley, 1902, Wilsonfontein, Damaraland, Namibia.
Sometimes placed in genus *Eremalauda*, but genetic evidence suggests that it falls within clade formed by members of present genus. Birds from C Namibia S to NW South Africa sometimes separated as race *gregaria*, but generally considered indistinguishable from those in rest of species' range. Monotypic.
Distribution. Angolan coastal plain (S from Porto Amboim, in Cuanza Sul), Namibia, SW Botswana and NW South Africa.



Descriptive notes. 13-14 cm; 16-22 g. Fairly small, very pale lark with erectile crest which, even when not raised, tends to make head appear slightly peaked; stout bill rather heavy along much of its length. Has pale face, appearing washed out, with whitish supercilium contrasting only slightly with buff-brown ear-coverts, faint darker T-shaped mark under eye (visible only at close range); pale to very pale sand-brown above, darker brown feather centres forming indistinct streaks, these most prominent on crown; wing-coverts dark brown with broad buffy margins, median coverts often show as row of darker spots; flight-feathers and tail darker brown with buffy margins, especially on inner secondaries, tertials and central tail feathers, outer rectrices broadly edged white; underparts white, buffy wash and a few darker brown streaks on breast; eyes brown, bill whitish horn-coloured, tip darker; legs pale flesh. Distinguished from *S. conirostris* by slightly larger size, paler and less brown upperparts, much longer, paler bill; from *S. sclateri* by paler plumage above and below, somewhat shorter and less heavy bill. Sexes alike. Juvenile has white tips and darker subterminal bars on upperpart feathers, appearing slightly darker and more spotted, breast diffusely spotted. Voice. Male song, in flight, a long, rambling series of rather unmelodic chirps and trills, with occasional sweeter whistles, most phrases repeated 3-5 times before switching to new phrase. Soft "chipping" call in flight or when flushed; "tree" call when nest approached by intruder; soft "chop chop" feeding call to nestlings.
Habitat. Arid and semi-arid grassy plains, usually preferring gravels and hard limestone to sands. Often occurs in areas with some shrubs or scattered trees.
Food and Feeding. Seeds, insects and green vegetable matter. In one study in C Namib Desert, seeds made up 77% of diet, with insects 19% and green vegetable matter 4%; seeds were mostly those of grasses, with some forbs, and insects were mostly termites (of genus *Hodotermes*) and ants, with smaller numbers of beetles (Coleoptera), bugs (Hemiptera), flies (Diptera), solifugids and spiders. Unusually, chicks, even from hatching, fed mostly with green seeds. Forages on the ground, singly or in small flocks of up to ten birds; occasionally in aggregations of hundreds or thousands, often mixed with *Eremopterix verticalis* and Lark-like Buntings (*Emberiza impetuani*). Creeps along, picking prey from surface, or digs with its bill; also pulls at grass stems to expose succulent bases, which are then eaten. Seeks shade in heat of day, or sometimes reduces heat stress by standing with wings drooped, facing into wind, on elevated perch. Regularly drinks water, especially in hot, dry weather, but some flocks apparently survive without access to water in C Namib. Metabolic rate typical for a bird of its size, but rate of evaporative water loss significantly lower than expected, also significantly lower among birds deprived of water. Some individuals maintained constant weight on a diet solely of dry millet seeds or with only 0·3 M salt solution to drink; water-deprived birds produced faecal pellets containing 52% water.
Breeding. Breeds opportunistically after rains, mostly Mar-May, but can occur at any time; typically starts 4-8 weeks after rain events, thus somewhat later than other nomadic species in its range, e.g. *Eremopterix australis* and *E. verticalis* and Lark-like Bunting, possibly because of nestling diet (seeds); in N & NW Karoo, abundance of *Stipagrostis* awns (used for nest-lining) may be indicator of suitable breeding conditions. Monogamous; nests singly, but often at fairly high densities when conditions favourable. Male performs protracted aerial display, rising steeply 50-100 m and singing continuously while circling or flying slowly into wind, usually ending by dropping straight down to ground, often to chase another bird; on ground, approaches female with raised crest and wings slightly drooped, bobbing its head and singing continuously. Nest in shallow scrape on ground, usually at base of a grass tuft, other plant or rock, typically on S or E side for shelter from afternoon sun, those in winter often more exposed, cup mostly lined with grass awns, rim adorned with pebbles, soil clods and occasionally sand-encrusted spider webs. Clutch 2-4 eggs (mean 2·7); incubation by both sexes, period 11-13 days; chicks well camouflaged by having long, silky down that matches feathery grass awns of nest-lining, brooded and fed by both parents; when nest approached, parents flutter erratically over intruder, calling and sometimes snapping the wings, frequently landing and taking off again, if intruder persists they may feign injury by fluttering away along ground; chicks leave nest at c. 10 days, before able to fly. Of 12 eggs in six nests in Kalahari, only four hatched and no chicks fledged.
Movements. Nomadic; large flocks follow rain events.
Status and Conservation. Not globally threatened. Common to locally abundant in its core range, but occurrence erratic towards periphery. Densities difficult to assess because of nomadic behaviour; 5-12 birds/ha in C Namib when conditions favourable. Foraging flocks sometimes very large, containing several thousands of individuals. Significant numbers occur in protected areas in Namibia and Kalahari; given the species' wide-ranging movements, however, this fact is considered insufficient to ensure its conservation.
Bibliography. Brewster (1998), Dean (1997, 2000), Demey (2004a, 2004c), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Keith *et al.* (1992), Lloyd (1999), Mackworth-Praed & Grant (1962), Maclean (1970a, 1970b, 1993a), Sinclair & Hockey (1996), Sinclair & Ryan (2003), Tarboton (2001), Willoughby (1968, 1971).

81. Pink-billed Lark

Spizocorys conirostris

French: Alouette à bec rose **German**: Rotschnabellerche **Spanish**: Alondra Piquirrosa

Taxonomy. *Alauda conirostris* Sundevall, 1850, Vetchkop, Free State, South Africa.
Has been thought to form a superspecies with *S. sclateri*, but usually considered closer to *S. fringillaris*. Geographical variation broadly clinal; several races possibly not sustainable. Birds from far S of range named as race *transiens* and others from NE South Africa as *griseovinacea*, both regarded as indistinguishable from nominate. Six subspecies recognized.
Subspecies and Distribution.
S. c. makawai (Traylor, 1962) - W Zambia (Liuwa and Mutala Plains).
S. c. harti (Benson, 1964) - SW Zambia (Matabele Plain).
S. c. damarensis Roberts, 1922 - N Namibia and NW Botswana.
S. c. crypta (Irwin, 1957) - NE Botswana (Makgadikgadi Pan and L Dow).
S. c. barlowi Roberts, 1942 - S Namibia, S Botswana and NW South Africa (Northern Cape).
S. c. conirostris (Sundevall, 1850) - South Africa (Northwest Province E to Mpumulanga and W KwaZulu-Natal, S to Free State and Eastern Cape) and NW Lesotho.

Descriptive notes. 12-13 cm; 12-17 g. Fairly small, compact lark with short, stout, pinkish bill. Nominate race has broad buffy to whitish supercilium, contrasting dark eyestripe and streaked brown crown; upperparts brown to rufous-brown with darker feather centres, plainer on rump and uppertail-coverts; upperwing-coverts dark brown with broad buffy margins, median coverts often appearing as row of dark spots on folded wing; flight-feathers dull brown with buff margins, latter broader on inner secondaries and tertials; tail dark brown, buff margins of outer feathers; throat whitish, rest of underparts rufous-buff, breastband of dark brown streaking; eyes pale brown; bill dull pink; legs pink. Differs from *S. fringillaris* in bolder supercilium, warmer-coloured upperparts, less pale in outer tail, darker underparts, thicker bill. Sexes alike. Juvenile is darker above, appearing spotted owing to pale feather tips, breast with diffuse dark spots, bill duller with blackish tip. Races vary chiefly in coloration, paler and less streaked in arid W, more rufous in SE, greyer or blackish above in N: *barlowi* is paler than nominate, less streaked above, belly whitish; *damarensis* is paler and less streaked than previous; *crypta* has greyer upperparts; *makawai* is blackish-brown with pinkish-buff edgings above, light pinkish-chestnut below; *harti* resembles previous but paler, with upperparts feathers edged pale grey. Voice. Flight call a dry, trilled "chree chree", higher-pitched than that of *Calandrella cinerea*; male song a mix of call notes and short, sweeter, whistled elements, often repeating each note 3-4 times.
Habitat. Ranges from moist submontane grassland to semi-arid Nama Karoo and Kalahari grassland and savanna. In E occupies pastures and fields with young cereal crops, as well as recently ploughed and fallow fields. Largely restricted to red sands in the Kalahari, where prefers well-grassed dunes but also occurs in *Rhigozum* scrub provided that sufficient cover present. Often found around pans or on floodplains with short grass in N Botswana and SW Zambia.
Food and Feeding. Mostly seeds, some insects. Forages on the ground, singly or in pairs; in small flocks outside breeding season. Walks with bent legs, inspects ground surface. Regularly drinks water.

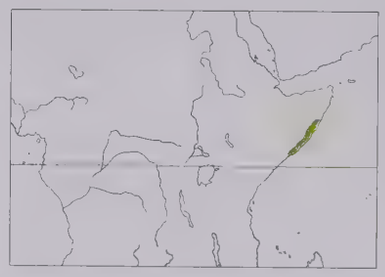
Breeding. Mostly Nov-Jun, in association with summer rains, generally later in NW (where onset of rains delayed); in arid W breeding opportunistic, linked to rainfall, can take place at any time of year. Monogamous; nests solitarily, when conditions favourable also in loose aggregations. Male has fairly short aerial display. Nest a shallow scrape in soft, sandy soil, usually at base of a grass tuft, occasionally of another plant, lined with cup of grass and rootlets, sometimes built on foundation of sticks, in bare sandy areas open side typically with broad "apron" of nest material; usually facing S or E, but some nests in winter are in exposed sites. Clutch 2 eggs, rarely 3 (mean 2·1); incubation starts immediately after first egg laid, lasts 11-13 days, usually 12 days; chicks fed by both parents, leave nest at c. 10 days, before able to fly. In the Kalahari, crude breeding success was 15% (48% of eggs hatched, 31% of chicks fledged).
Movements. Nomadic in arid W, following rain events with other granivorous species. Largely resident or subject to local movements elsewhere in range. Localized population in NE assumed to be entirely sedentary.
Status and Conservation. Not globally threatened. Locally common in S, becoming more sporadic in N. Non-breeding flocks small. Lives in transformed habitats as well as natural ones.
Bibliography. Benson *et al.* (1971), Clancey (1964b, 1972), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Herholdt & Grobler (1987), Keith *et al.* (1992), Lloyd (1998), Mackworth-Praed & Grant (1962), Maclean (1970a, 1970b, 1993a), Penry (1994), Sinclair & Hockey (1996), Sinclair & Ryan (2003), Tarboton (2001).

82. Botha's Lark

Spizocorys fringillaris

French: Alouette de Botha **German**: Finkenlerche **Spanish**: Alondra de Botha

Taxonomy. *Alauda fringillaris* Sundevall, 1850, Leeuspruit, Vredevort, Free State, South Africa. Sometimes placed in a monotypic genus *Botha*, but such treatment unwarranted. Usually considered closely related to *S. conirostris*. Monotypic.
Distribution. E Free State and Mpumulanga, in NE South Africa.



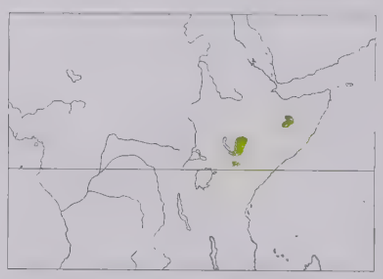
Descriptive notes. 13-14 cm; 16-21 g. Fairly small, compact lark with heavily dark-streaked upperparts. Has creamy or buffy supercilium, dark eyestripe, pale brown ear-coverts lightly mottled darker; upperparts grey-brown, heavily streaked blackish-brown; flight-feathers and upperwing-coverts dark brown with narrow buff margins; tail dark brown, outer two feathers with broad white edges; whitish below, breast and flanks washed rufous-buff, small dark brown streaks on breast; eyes brown; bill orange-pink, slightly darker tip; legs pink. Differs from *S. conirostris* in slightly larger size, narrower supercilium, colder upperparts, paler underparts, white (not buffy) tail side, smaller and less pink bill. Sexes alike. Juvenile is darker with buff feather fringes above, appearing spotted or scaled, bill horn-coloured. Voice. Male song, from ground or in flight, a rather dry "tchiree" or "teez-rrr". Flight call soft "tirrup tirrup" or "chuk", often in chorus by a flock; similar call also given on ground by flock-members prior to flushing.
Habitat. Short upland grassland, usually on clay soils. Favours well-drained, heavily grazed areas with occasional bare patches; often found near cattle pens and other trampled areas. Avoids tall grassland, fields, rocky areas and poorly drained sites.
Food and Feeding. Seeds and insects; all identifiable prey delivered to chicks were small insects, including beetles (Coleoptera) and moths (Lepidoptera). Forages singly or in pairs; in small flocks outside breeding season. Picks prey from ground or from grass; not seen to dig for food. Occasionally hawks aerial insects. Drinks regularly; apparently dependent on water sources, especially in hot, dry weather.
Breeding. Nov-Jan. Monogamous; nests solitarily, although inter-nest distance sometimes less than 50 m. Male aerial display, with slightly exaggerated wingbeats, 10-20 m above ground. Nest an open cup, lined with grass, sometimes with wool or hair, in shallow scrape on ground, usually between a couple of short grass tufts but completely open above; one nest was in a pile of sheep dung. Clutch 2 eggs, rarely 3 (mean 2·1); incubation by both adults, in relatively short bouts with frequent change-overs, duration not known; chicks brooded and fed by both parents, a single large chick was fed 11 times in 30 minutes, adults foraging mostly within 50 m of nest but also ranging more than 200 m, beyond other nests, without any aggressive interactions with other pairs; fledging period not known. Crude breeding success 53% (of 17 eggs in eight nests, nine survived).
Movements. Resident; local movement in response to fires.
Status and Conservation. ENDANGERED. Restricted-range species: present in South African Grasslands EBA. Maximum range covers c. 43,000 km², within which it is thinly distributed and patchy; recorded densities of up to 6 pairs/ha; in small flocks of 5-10 birds when not breeding. Global population estimated at 1500-5000 individuals, all on privately owned land, and assumed to be decreasing. Much of its habitat has been transformed by agriculture. Establishment of a Grassland Biosphere Reserve centred on Wakkerstroom, in Mpumulanga, would encompass a significant number of birds, but progress towards this goal has been slow. Conservation targets include research designed to gain better understanding of factors determining the species' distribution, and assessment of its sensitivity to different grassland-management practices, such as use of fire and different levels of grazing intensity.
Bibliography. Allan *et al.* (1983), Barnes (2000), Brooke (1984b), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Evans, S.W. (1999b), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Herholdt & Grobler (1987, 1988), Keith *et al.* (1992), Mackworth-Praed & Grant (1962), Maclean (1993a), Sinclair & Hockey (1996), Stattersfield & Capper (2000), Tarboton (2001), Vernon (1973).

83. Obbia Lark

Spizocorys obbiensis

French: Alouette d'Obbia **German**: Obbialerche **Spanish**: Alondra de Obbia

Taxonomy. *Spizocorys obbiensis* Witherby, 1905, Obbia, Somalia.
Monotypic.
Distribution. Coastal plain of C Somalia (from 50 km S of Jirriiban S to Halhambe).
Descriptive notes. 12 cm; 12-16 g. Small, compact lark with rather stout bill; crouched feeding posture, recalling a canary (*Serinus*) or other finch. Has prominent whitish supercilium (often not reaching bill anteriorly, also sometimes interrupted by eye), dark eyestripe, dark moustachial and malar stripes; small pale spot on forehead immediately above bill on some individuals; crown and upperparts brown, variably streaked darker brown; central tail brown, matching upperparts, rest of tail dark blackish-brown, outer feathers sometimes with narrow white edge; whitish below, regular blackish streaks on breast and flanks; eyes brown; bill mostly brown, paler yellow base; legs dull flesh-brown. Sexes alike. Juvenile undescribed. Voice. Flight call "tip-tip"; song unknown.



Habitat. Vegetated coastal dunes, also open coastal plain with heavily grazed grass and scrub farther inland; extends up to 40 km inland in N, to only 1 km in S.
Food and Feeding. Diet unknown; probably consists largely of seeds. Feeds on the ground, in typical crouched posture; also creeps over low mats of vegetation, in manner atypical for a lark.
Breeding. May-Jul and Nov-Dec in years with sufficent rainfall. Nest an open cup, variably lined with vegetation, fluffy seeds and even pieces of woolly string, in shallow scrape in sand at base of a plant, often on S or E side (providing little shade), or partly concealed under thin cover of creeping vegetation; few nests found have been close to the sea (of six sites detailed, four were within 50 m of high-water line). Clutch 2-3 eggs (mean 2·2); no information on parental duties or incubation and fledging periods.
Movements. Unknown. Possibly resident, but often occurs in flocks of up to 30 birds, even during breeding season; may be subject to local movements within its small range.
Status and Conservation. Not globally threatened. Data-deficient. Restricted-range species: present in Central Somali Coast EBA. No recent information on the species' status; was the most abundant passerine in coastal dunes in late 1970s. Largely dependent on vegetated dunes; some concern that increasing grazing pressure, coupled with demand for firewood, will lead to destabilization of its dune habitat, especially around Mogadishu. As its range extends over minimum of 570 km from N to S, it is likely to be still secure in at least some areas.
Bibliography. Ash (1981), Ash & Miskell (1998), Collar & Stuart (1985), Collar & Violani (1984), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Keith *et al.* (1992), Mackworth-Praed & Grant (1960), Sinclair & Ryan (2003), Stattersfield & Capper (2000).

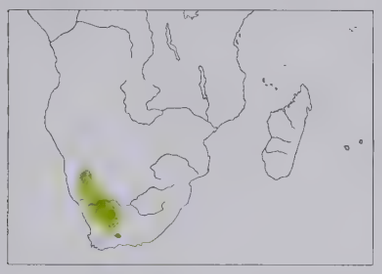
84. Masked Lark

Spizocorys personata

French: Alouette masquée **German**: Maskenlerche **Spanish**: Alondra Enmascarada

Taxonomy. *Spizocorys personata* Sharpe, 1895, Sassabana, Milmil, Ogaden, Ethiopia.
Four subspecies recognized.
Subspecies and Distribution.
S. p. personata Sharpe, 1895 - E Ethiopia.
S. p. yavelloensis (Benson, 1947) - S Ethiopia and N Kenya (S to Dida Galgalu Desert).
S. p. mcchesneyi (Williams, 1957) - Marsabit Plateau, in N Kenya.
S. p. intensa (Rothschild, 1931) - C Kenya.

Descriptive notes. 15 cm; 20 g. Smallish, dark lark with heavy, pinkish bill, distinctive black facial markings. Nominate race has black mask from base of bill to area around eye and extending down into broad malar band, latter with white central patch, and accentuated by pale anterior ear-coverts; crown and upperparts grey-brown with blackish central feather streaks, rump plainer, upperwing-coverts and tertials dark brown with broad cinnamon margins; flight-feathers and tail brown, outer rectrices broadly edged buff-cinnamon; throat white, breast greyish-brown, shading to rufous-brown on belly, buff undertail-coverts; eyes brown; bill pale pink or yellowish-horn; legs pale pink. Sexes alike. Juvenile undescribed. Races vary in coloration: *yavelloensis* is darker and greyer above, dark greyish breast contrasting more with rufous belly; *mcchesneyi* has browner upperparts darker than nominate; *intensa* is rich brown above, darker below, belly deeper reddish. Voice. Call, given on ground or in flight, described as rolling "chew-chi chew, chew", "tew tew tutew tew" or shorter "chew" or "chew-chew"; also high-pitched "treeeee" and repeated "tee tee tee".
Habitat. Arid plains on black or red lava and black-cotton soils. Prefers areas with little shrub or grass cover, but apparently avoids road edges. At 400-1600 m.
Food and Feeding. Grass seeds, bulbs and corms; also some insects, including grasshopper (Acrididae) egg cases. Feeds on the ground; presumably used heavy bill to dig for bulbs and corms. Often stands erect on rocks, possibly to reduce heat stress.
Breeding. One specimen with well-developed egg in oviduct in Jul. No other information.
Movements. Poorly known; presumably resident and locally nomadic.
Status and Conservation. Not globally threatened. Locally common. Poorly known species; fieldwork required in order to ascertain details of breeding biology and ecology. Occurs in several protected areas, including Shaba Game Reserve, in C Kenya.
Bibliography. Bennun & Njoroge (1999), Benson (1946a), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960), Short *et al.* (1990), Sinclair & Ryan (2003), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).



85. Sclater's Lark

Spizocorys sclateri

French: Alouette de Sclater **German**: Ammernlerche **Spanish**: Alondra de Sclater
Other common names: Sclater's Short-toed Lark

Taxonomy. *Calandrella sclateri* Shelley, 1902, Hauntop River, Maltahöhe, Namibia.
Has been thought to form a superspecies with *S. conirostris*. In South Africa, birds from Bushmanland (c. 40 km E of Pofadder) described as race *theresae* and others from SE as *capensis*, but both regarded as inadequately differentiated. Best treated as monotypic.

Distribution. Nama Karoo of S Namibia and W South Africa.

Descriptive notes. 13-14 cm; 17-21 g. Fairly small, buffy lark with rather large-headed appearance, remarkable wedge-shaped bill that is long and heavy along most of length and looks slightly uptilted. Dark eyestripe contrasts with buffy supercilium which extends onto forehead; distinctive dark T-shaped mark or "teardrop" under eye; ear-coverts brown; rather uniform buffy brown above, darker brown streaks on crown and upperparts; flight-feathers darker brown, pale buff edges and tips to secondaries; tail dark brown, outer 2-3 feathers with whitish on outer webs broadening towards base (in flight, showing as dark central triangle with white inverted triangles at edges, similar to tail pattern of a *Cercomela* chat); throat whitish, pale buffish-white below, breast with darker brown streaks; eyes brown (often held partly closed); bill horn-brown, base yellowish-horn; legs flesh-brown. Differs from *S. starki* in darker appearance, longer bill, no erectile crest; from *S. conirostris* in dark T-mark on face, much longer bill. Sexes alike. Juvenile is more boldly patterned, with white tips and dark subterminal bars on back and crown feathers, buff-edged upperwing-coverts, flight-feathers and tail with whitish tips, spotted below (some white tips), T-shaped facial mark less prominent. Voice. Soft "prrp prrp" or "prrp prrp treep" call, primarily in flight, also on ground during foraging; displaying male utters similar calls.

Habitat. Stony plains with ephemeral grasses and scattered bushes. Often in areas with very little vegetation, and very few other bird species, but generally remains fairly close to water sources; usually nests within easy commuting distance of drinking water. Apparently roosts in shallow depressions in open gravel plains.

Food and Feeding. Insects and seeds. Adults feed extensively on large seeds of the ephemeral eight-day grass (*Enneapogon desvauxii*) that are produced singly in bases of leaf sheaths, where well protected from most granivores; consequently, this food resource is available for protracted periods following rainfall events, allowing this lark to be less nomadic than other arid-country granivorous birds in its range. Chicks fed almost entirely with insects, including large numbers of harvester termites (Isoptera), as well as a few caterpillars and once a small butterfly (Lepidoptera). Feeds on the ground, singly or in pairs, outside breeding season in small flocks of up to 30 individuals; has slow, somewhat ponderous gait. Uses heavy bill to flip over small stones and search for insects beneath; also extracts seeds directly from grasses. Regularly visits water to drink.

Breeding. Primarily in Aug-Dec, sometimes from Jun, and usually well synchronized at any one site; largely independent of rainfall, and even some evidence that breeding activity depressed following good rains, despite apparently increased abundance of insects (for chick-feeding) at such times. Monogamous; solitary, but nests can be less than 10 m apart. Male has low display flight with slow, exaggerated wingbeats and depressed tail. Nest-site unusual, in open gravel plain well away from vegetation, although sometimes next to a small stone (may provide visual reference for the birds); excavates fairly deep depression in ground, using the legs and wings, sometimes several scrapes made before final one selected for use, scrape usually lined with small stones and then dry grass and feathery grass awns, usually a broad "apron" of small stones (up to 200) and grass carefully placed around rim (thought to break up outline of nest and conceal signs of excavation, making it less visible to predators). Clutch invariably 1 egg, clutch size unaffected by rainfall; incubation by both parents, usually in fairly short shifts, change-overs particularly frequent, every 10 minutes, in very hot weather, sitting bird does not leave nest to defecate (droppings accumulate on rim), incubation period 11-13 days; newly hatched chick brooded by both parents for several days, brooding adult sitting extremely tight, almost allowing itself to be touched, when parent does leave nest chick is partly protected by its resemblance to a collection of grass seeds; fed by both parents, up to 17 meals per hour, in hot weather shaded by one parent standing erect over it and typically awaiting return of food-carrying partner before leaving, thus slowing feeding rate to only 10 meals per hour; chick leaves nest after 10-12 days, occasionally up to 14 days, before able to fly. Breeding success generally low owing to high rate of nest predation, mostly by small mammals such as mongooses (Herpestidae); only 37% of clutches survive to hatching date, and 80% of these hatch, then 78% of broods survive to fledge, giving overall breeding success of 20% and mean of 0·2 young fledged per attempt; heavy rain can flood nest, killing chick.

Movements. Virtually resident in some areas, but subject to irregular movements, especially towards edges of range. Occasional vagrancy indicated by record of a single juvenile in SW South Africa (near Cape Town).

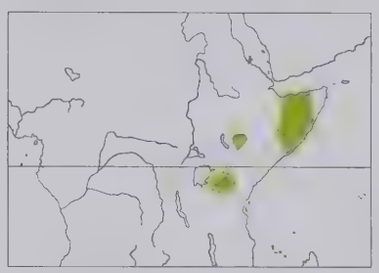
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Scarce and local, and patchily distributed. Non-breeding flocks only small, up to 30 individuals. No evidence of any decrease in range or population. Factors affecting this species' distribution not understood; could be adversely affected by livestock grazing, although it may also have benefited from creation of watering points for livestock. Population dynamics require further investigation; need for one parent to shade chick during heat of day, thereby limiting food-delivery rate, has been suggested as reason for small clutch size, but several other alaudids manage to raise two chicks in even more extreme conditions, e.g. *Eremopterix nigriceps* in Saudi Arabia. High predation risk may also explain small clutch size (bet-hedging); siting of nest away from vegetation likely to be an adaptation to minimize nest losses to terrestrial predators, which routinely search around base of shrubs and grass tufts.

Bibliography. Barnes (2000), Brooke (1984b), Collar & Stuart (1985), Dean & Colston (1988), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Hockey & Sinclair (1981), Keith *et al.* (1992), Lloyd (1997, 1999), Mackworth-Praed & Grant (1962), Maclean (1993a), Sinclair & Hockey (1996), Stattersfield & Capper (2000), Steyn & Myburgh (1989, 1991), Tarboton (2001), Winterbottom (1972b).

Genus *PSEUDALAEMON* E. L. Phillips, 1898

86. **Short-tailed Lark**

Pseudalaemon fremantlii



French: Cochevis à queue courte **German**: Bartlerche **Spanish**: Alondra Colicorta

Taxonomy. *Calendula fremantlii* E. L. Phillips, 1897, Gedais, Somalia.

Peculiar lark of uncertain affinities. Has sometimes been placed in genus *Galerida*, and considered by some to form a superspecies with *G. modesta* and *G. magnirostris*, but differences too great for such treatment to be warranted. Three subspecies recognized.

Subspecies and Distribution.

P. f. fremantlii (E. L. Phillips, 1897) - Somalia and SE Ethiopia.
P. f. megaensis Benson, 1946 - S Ethiopia and N Kenya.
P. f. delamerei Sharpe, 1900 - S Kenya and N Tanzania.

Descriptive notes. 14-15 cm; male 23-26 g, female 19-25 g. Peculiarly short-tailed lark with large head and long, heavy bill. Nominate race has well-marked face, with buffish-white supercilium, dark eyestripe, and black crescent and vertical line under eye; heavily streaked above, with blackish-brown feather centres contrasting with pale buff-brown margins; flight-feathers grey-brown with narrow pale outer edges; tail dark brown, outer feathers with white outer webs, central feathers with broad grey-brown margins; whitish below, breast with blackish breast streaks that coalesce to form small patch at side of breast; eye pale hazel brown; bill horn-brown, paler yellowish base of lower mandible; legs whitish or straw-pink. Sexes alike. Juvenile has white feather tips on upperparts, diffuse brown spots on breast. Races differ in upperpart coloration and extent of streaking: *megaensis* is darker than nominate, upperparts more heavily streaked blackish and with more rufous feather edges, breast and sides more reddish-brown; *delamerei* resembles previous but more greyish-brown above, variable, some individuals more rufous-brown. Voice. Song, from ground, a rather slow series of mournful and sometimes slurred whistled notes, both ascending and descending in pitch. Calls "tewi" on flushing; also softer "chip" contact calls.

Habitat. Semi-arid grassland and open dry woodland, often at edge of grassy plains where some rocks and low shrubs present, from near sea-level to 1800 m in Somalia. Races *megaensis* and *delamerei* restricted to short, heavily grazed grassland and semi-arid scrub above 1000 m, to c. 1700 m; attracted to burnt areas.

Food and Feeding. Seeds, bases of grass leaves, corms, and at least some insects. Forages on the ground, singly or in pairs; in small flocks outside breeding season, sometimes in loose association with *Calandrella* larks. Often digs in ground or into bases of grass tufts with its long, heavy bill. Seeks shade under bushes during heat of day.

Breeding. Poorly known. Breeds May-Jun. Only two nests described, each in centre of grass tuft; clutch 3-4 eggs; nothing known about parental duties or incubation and fledging periods.

Movements. Resident and local nomad.

Status and Conservation. Not globally threatened. Locally common; occasionally abundant in Somalia, where non-breeding flocks of up to 50 birds recorded. Possibly less numerous in Kenya and Tanzania, where typically observed in pairs or small groups. Present in several protected areas, e.g. Serengeti and Arusha National Parks (Tanzania).

Genus *GALERIDA* Boie, 1828

87. Crested Lark
Galerida cristata

French: Cochevis huppé **German**: Haubenlerche **Spanish**: Cogujada Común
Other common names: Common Crested Lark

Taxonomy. *Alauda cristata* Linnaeus, 1758, Europe = Vienna, Austria.
Subspecific taxonomy extremely complex, with over 60 races described across species' huge range, seemingly a result of its mostly sedentary habits, and strong correlation of plumage ground colour and intensity of streaking with environmental factors (mainly soil colour, perhaps also general conditions of aridity and amount of sunshine); even within range of a given race, highly localized populations showing quite different colour, related to aberrantly coloured local soils, occur (e.g. within range of olive-grey *apuliae* in S Italy, ash-grey birds from E Calabria named as "*heraelaciniae*"); also well-marked variation, tending to be clinal, in body size, wing length and, especially, bill length. In general, differences among races slight and often noticeable only if large series of skins in fresh plumage compared, as many taxa described on basis of small number of specimes, sometimes variably abraded; intergradation also evident, both in Palearctic and in Afrotropics. Birds from NW Spain sometimes attributed to nominate race. Several attempts at "lumping" undertaken, in some cases reducing number of races to just 20, but results seem often too arbitrary, and perhaps preferable to recognize described races unless very compelling reasons exist to merge them with others. Geographical areas of especial difficulty, where several races meet and establishment of neat frontiers among them appears impossible, include Morocco, Nile Valley, Near East and Asia Minor. Thorough review needed. Besides listed races, others described include *madaraszi* from S Croatia (Dalmatia) and *muehlii* from Greece, both included in *meridionalis*; *moltschanowi* from Crimea, in *tenuirostris*; *ioniae* from W Asia Minor (Izmir region), *magdae* from S Caspian region and *submagna* from Transcaspia, all in *caucasica*; *weigoldi* and *ankarae* from Asia Minor, in *subtaurica*; *retrusa* from N China (Gansu) and *alaschanica* from Inner Mongolia (Alxa), in *magna*; *vamberyi* from Kara Kum Desert (Turkmenistan), in *iwanowi*; *gafsae*, *whitakeri* and *deprimozi* from Tunisia, all in *arenicola*; *deltae* from Nile Delta, in *nigricans*; *imami* from Yemen and *thomsi* from N Oman (Muscat), in *tardinata*; *moeritica* from N Egypt (Faiyum), in *maculata*; *caroli* from Egypt, *nubica* from Ethiopia and *eritreae* from Eritrea, all in *altirostris*; and *courtoti* from W Chad and *zalingei* from W Sudan, both in *alexanderi*. Thirty-seven subspecies provisionally recognized.
Subspecies and Distribution.
G. c. cristata (Linnaeus, 1758) - C Europe from Denmark and extreme S Sweden E to Belarus, S to France, N Italy, N former Yugoslavia, N Hungary and N Ukraine.
G. c. pallida C. L. Brehm, 1858 - Iberian Peninsula.
G. c. neumanni Hilgert, 1907 - W Italy (Toscana S to Rome area).
G. c. apuliae von Jordans, 1935 - S peninsular Italy and Sicily.
G. c. tenuirostris C. L. Brehm, 1850 - E Hungary and Romania E to S Russia (S to N Caucasus region) and W Kazakhstan.
G. c. meridionalis C. L. Brehm, 1841 - S formerYugoslavia S to Greece (including Ionian Is and Crete) and W Turkey.
G. c. caucasica Taczanowski, 1888 - E Aegean Is (Samothraki S to Samos), N Turkey, S Caucasus and W Transcaucasia.
G. c. subtaurica (Kollibay, 1912) - C Turkey E to S Transcaucasia, NW Iran and W Turkmenistan, S to N & E Iraq.
G. c. cypriaca Bianchi, 1907 - Rhodes, Karpathos and Cyprus.
G. c. zion Meinertzhagen, 1920 - S Turkey, Syria, E Lebanon and E Israel (S to Jerusalem).
G. c. cinnamomina Hartert, 1904 - W Lebanon (S from Beirut) and NW Israel (Mt Carmel and Haifa).
G. c. magna Hume, 1871 - S Kazakhstan E to S Mongolia and N China (Xinjiang E to N Gansu and Inner Mongolia).
G. c. leautungensis Swinhoe, 1861 - Manchuria and NE China.
G. c. coreensis Taczanowski, 1888 - Korea.
G. c. iwanowi Loudon & Zarudny, 1903 - C Turkmenistan and C & S Iran E to S Tadjikistan, Afghanistan and NW Pakistan.
G. c. lynesi Whistler, 1928 - N Kashmir (Gilgit Valley).
G. c. kleinschmidti Erlanger, 1899 - NW Morocco (E to Rif Mts, S to Middle Atlas).
G. c. riggenbachi Hartert, 1902 - W Morocco (Casablanca S to Sous Valley).
G. c. carthaginis Kleinschmidt & Hilgert, 1905 - coastal region from NE Morocco E to N Tunisia (E to Sousse).
G. c. randoni Loche, 1860 - Hauts Plateaux of E Morocco (E of upper R Moulouya) and NW Algeria.
G. c. macrorhyncha Tristram, 1859 - S Morocco and NW Algeria S of Atlas Saharien (E to Laghouat and Ghardaia) S to WC Mauritania (Atar area).
G. c. balsaci Dekeyser & Villiers, 1950 - coastal Mauritania.
G. c. arenicola Tristram, 1859 - NE Algerian Sahara (E from Biskra and Ouargla), S Tunisia (S of Gafsa and Sfax) and NW Libya (Tripolitania).
G. c. helenae Lavauden, 1926 - SE Algeria and probably neighbouring SW Libya.
G. c. festae Hartert, 1922 - coastal NE Libya (Benghazi E to Tubruq).
G. c. brachyura Tristram, 1865 - NE Libya (inland Cyrenaica), coastal N Egypt (E to Alexandria), and from N Sinai Peninsula and S Israel (Negev and Dead Sea region) E to S Iraq and N Saudi Arabia.
G. c. nigricans C. L. Brehm, 1855 - N Egypt (Nile Delta).
G. c. maculata C. L. Brehm, 1858 - Nile Valley from Cairo S to Aswan (Egypt).
G. c. halfae Nicoll, 1921 - Nile Valley from Aswan S to extreme N Sudan (Wadi Halfa).
G. c. senegallensis (Statius Muller, 1776) - S Mauritania, Senegambia and Guinea-Bissau E to Niger.
G. c. jordansi Niethammer, 1955 - N Niger (Aïr Mts).
G. c. alexanderi Neumann, 1908 - N Nigeria E to W Sudan, and NE Central African Republic.
G. c. isabellina Bonaparte, 1850 - C Sudan (Kordofan E to R Nile).
G. c. altirostris C. L. Brehm, 1855 - E Sudan (E from Nile Valley) and Eritrea.
G. c. somaliensis Reichenow, 1907 - N Somalia, S Ethiopia and N Kenya.
G. c. tardinata Hartert, 1904 - S (perhaps also W) Arabia.
G. c. chendoola (Franklin, 1831) - S Kashmir foothills S to E Pakistan, W & N India (E to Bihar) and S Nepal.

Descriptive notes. 17-19 cm; c. 35-50 g. Medium-sized, rather bulky lark with prominent long, spiky crest, rather long bill, relatively short and broad wings rounded at tip, very short primary projection, narrow and pointed at tip outer primary reduced (0-8 mm short of tip of primary coverts), rather short tail, hind claw long (9-14 mm) and straight. Nominate race has buff-white supercilium and eyering, dark eyestripe and moustachial and malar stripes; crown and upperparts buffish grey-brown, heavily streaked dark brown, hindneck and rump less streaked; flight-feathers olive-brown, narrowly edged buffish to light cinnamon; tail with olive-brown central feathers, remainder black, except for distinctive buff-brown outer feathers; whitish below, more buff on breast side and flanks, broad blackish spot-like streaks on breast, narrow and more diffuse streaks on flanks; axillaries and underwing-coverts rusty (noticeable in flight); bill dark horn above, pale yellow-flesh below; legs pale flesh. Distinguished from very similar *G. theklae* mainly by slightly longer and paler bill, somewhat less well-defined streaking below, rusty underwing. Sexes similar. Juvenile has shorter crest, upperparts spotted white, chest spotted rather than streaked, outer primary broader and longer (from 2 mm short of to 6 mm beyond tips of primary coverts). Races differ mainly in ground colour of plumage (rather constant over large areas in N populations, often marked changes from very dark to very pale in S), intensity of streaking, also in bill size and shape (bill rather short, about half of head length, in Europe, Middle East and NE Africa, to very long, almost equal to head length, in NW Africa), and wing length (longer in Asiatic races), following details only a very rough guide: *pallida* is slightly paler than nominate, less clearly streaked, in S also smaller and more reddish-tinged; *neumanni* is more rufous-brown above, deeper buff below, streaking more distinct, wing shorter; *apuliae* is generally paler and greyer above, broad streaks poorly defined, breast tinged pinkish with heavy sharp streaks; *meridionalis* is slightly darker than nominate; *tenuirostris* has upperparts cold brownish-grey with slight buff tinge, streaks well defined, wing slightly longer, bill longer and usually thinner; *caucasica* resembles previous, but bill usually shorter and heavier; *subtaurica* is rather pale greyish with olive to isabelline tinge above, narrow brown streaks, breast with fairly heavy black spots; *cypriaca* is smaller and darker than previous, streaking heavier and sharper, bill shorter and thinner in E (Cyprus); *zion* is tinged cinnamon above, streaks quite broad and dark (paler and fainter in E), breast spotting thin; *cinnamomina* is darker than last, sandy cinnamon with narrow brown streaks above, heavier blackish streaks on breast; *magna* is pale and relatively plain, buffish with little streaking above, paler with few narrow streaks below; *iwanowi* differs from last in grey-tinged upperparts with more streaks, more streaks below; other Asian races generally greyer and well streaked in E (*leautungensis*, *coreensis*), colder grey-brown (*lynesi*) or sandy brown (*chendoola*) and well streaked in S; *kleinschmidti* is very like nominate, but darker with more distinct black streaks above, breast tinged light cinnamon with heavier black streaks, shorter wing; *riggenbachi* has cinnamon-brown upperparts well streaked, heavily streaked cinnamon-buff breast, short bill; *carthaginis* is more buff with narrower streaks, paler below, longer wing; *randoni* differs from last in larger size, longer bill, heavier streaking; *macrorhyncha* has streaking paler than last, appears more uniform; *arenicola* is like previous but still paler and sandier, also smaller, bill shorter; *festae* is cinnamon-rufous with well-defined narrow dark streaks above, cinnamon-buff below, breast heavily streaked; *brachyura* is greyish sandy above; *helenae* is plain reddish-brown above, rufous-buff below, large brown breast spots; *nigricans* is darkest race, dark olive-grey and heavily streaked above, light cinnamon below, broad black breast streaks extending to flanks; *maculata* is somewhat paler than last, streaks narrower and less dark; *halfae* resembles previous, but paler and greyer; *senegallensis* has pale greyish-brown upperparts with variable dusky streaking, off-white below, breast with buff wash and obvious dark streaks; *balsaci* resembles previous, but paler below; *jordansi* is rather plain rufous-brown above, rufous-buff below, with small, narrow spots or streaks on breast; *alexanderi* is brownish with cinnamon tinge above, lightly streaked, buffish-white below, breast dark-streaked; *isabellina* has light grey-brown upperparts strongly tinged cinnamon, only faintly streaked, very pale and almost unmarked below; *altirostris* is rather pale sandy brown above; *tardinata* is extremely similar to previous, perhaps marginally darker; *somaliensis* is duller and greyer than last. Voice. Male song, from ground or low perch or in flight, a long and varied combination of whistles, tremolos, twitters and double notes, rather soft and melancholic, often containing imitations of other birds; like song of *Alauda arvensis* but shorter, less musical, with separate strophes, very similar to *G. theklae* song but slightly less varied. Commonest call a fluty, musical, rather desolate "twee-tee-too"; flight call gentle "too-ee".
Habitat. In most of range, typical species of dry plains with sparse vegetation cover and dry cultivations; perhaps originally inhabited warm semi-desert and steppe, secondarily human-modified landscapes. Habitats include open farmed countryside in N Mediterranean Basin, alpha (*Stipa tenacissima*) steppe and deserts in N Africa and Middle East, and sandy semi-desert and dry cultivations in India; also forest clearings; also savanna in Afrotropics. Requires high amount of bare ground or dry pasture, covering c. 50 % of surface. Often found along roadsides and in similar open, dry places, e.g. railway yards. Mainly low or middle altitudes, usually avoiding mountain areas, but to 1500 m in Spain, 2000 m in Russia and above 2300 m in W Pakistan.
Food and Feeding. Invertebrates, seeds and green material; mainly invertebrates in spring-summer and seeds during autumn-winter. Very wide assortment of invertebrates taken, mostly beetles (Coleoptera) but also grasshoppers (Acrididae), ants, caterpillars, snails and spiders. Seeds mainly those of weeds, but also cereal grain; seems to prefer seeds less than 1·4 mm in diameter. Nestlings fed exclusively with invertebrates. Forages on ground, singly or in pairs; outside breeding season also in small groups, sometimes with other alaudids. Searches the ground for items, also digging holes up to 2 cm deep; digs in horse dung. Breaks open snail shells by smashing them against stone or similar hard object. Apparently needs to drink water.
Breeding. Season mainly Mar-Jun/Jul in N parts of range, from Apr in Spain; in Afrotropics, laying Sept-Jun in Senegambia, Apr-May in Mali, Nov-Mar and May in Nigeria, Dec-Mar in Ethiopia, Apr-May in Somalia, Mar in E Africa; breeds Mar-Aug in Pakistan and India; often 2-3 broods per year. Monogamous, but one nest (with anomalous clutch size) recorded as attended by three birds; solitary and territorial. Male song flight typically at heights of c. 30-70 m, sometimes 100-200 m, average duration c. 3-4 minutes but up to 37 minutes recorded. Nest built by female alone, untidy lining of grass or other vegetation placed in depression on ground, openly or beside shrub, internal diameter 5-8 cm; nests of first clutches more robust and elaborated, sometimes domed. Clutch 3-5 eggs, occasionally 6 (mode 3 N Africa, 4 Turkmenistan, 5 Israel); replacement laid if clutch de-

On following pages: 88. Thekla Lark (*Galerida theklae*); 89. Malabar Lark (*Galerida malabarica*); 90. Sun Lark (*Galerida modesta*); 91. Sykes's Lark (*Galerida deva*); 92. Large-billed Lark (*Galerida magnirostris*); 93. Eurasian Skylark (*Alauda arvensis*); 94. Oriental Skylark (*Alauda gulgula*); 95. Raso Lark (*Alauda razae*); 96. Woodlark (*Lullula arborea*).

stroyed or lost; incubation by female alone, beginning with last or penultimate egg, period 11-13 days; chicks fed and cared for by both parents, nestling period 9-10 days in xeric environments, 12-13 days in mesic ones; young begin first flights at 15-16 days, capable of full flight at c. 20 days. Breeding success variable, often low, nestling mortality 30-40 % or more; eggs and chicks often taken by terrestrial predators. Nest in Pakistan held full clutches of both present species and *Calandrella raytal*, both of which incubated; fledged juvenile in France fed by Yellow Wagtail (*Motacilla flava*).

Movements. Predominantly resident. Sedentary in much of range; some dispersive movement in C Europe and Mediterranean region. Partially migratory or fully migratory in N part of Asian range; wintering grounds from Saudi Arabia E to Pakistan and India; some of those farther E move to C & S parts of breeding range in E Asia. Accidental in Europe, in Britain, Finland and Malta; also recorded Canary Is, and Chad.

Status and Conservation. Not globally threatened. Widespread and common in many parts of huge range, extent of which is almost largest of all alaudids (second only to that of *Eremophila alpestris*). In Europe, highest estimated populations in Spain (400,000-1,000,000 pairs), Russia and Bulgaria (each 100,000-1,000,000), Italy and Romania (each 200,000-400,000), Hungary (50,000-100,000), Greece (50,000-200,000) and Portugal (10,000-100,000); relatively small populations now left in France (15,000-25,000), Germany (12,000-18,000), Poland (3000-5000), Czech Republic (1100-2200) and Austria (150-200 pairs); recorded densities decrease markedly from S to N and from E to W, from 0·47 birds/ha in best habitats in Spain to 0·05-0·07 pairs/ha in Denmark and to 0·02-0·03 pairs/ha in Germany. Widespread and very common over much of Turkey (over 3,000,000 pairs estimated) and in Cyprus; common in Lebanon, very common in N Jordan (far fewer in S) and widespread in Israel (a few thousand pairs); widespread and very common in Iraq, and breeds commonly in Kuwait in years of good rainfall; very common in Arabia, commonest and most widespread lark in N Yemen. Common and very widespread in Pakistan, fairly common to locally common in rest of Indian Subcontinent range (but rare in E Nepal); common in suitable terrain in China (less so in winter). In African range, one of commonest larks in N, and abundant in Egypt; locally common to very common from Senegambia E to Sudan, Ethiopia and Somalia; fairly common in Kenya. Widespread decline, both in range and in numbers, recorded in W & C Europe, following marked range expansion in second half of 19th century and early 20th century (when colonized S Fennoscandia), and now extinct in several countries; last bred in Norway in 1972, Luxembourg in 1973, Sweden in 1989, Switzerland in 1990; not recorded since 1993 in Lithuania, and very low populations remaining in Denmark (15-17 pairs in 1999, decrease from 300-500 in 1988), Netherlands (below 400 pairs in 1991, 3000-5000 in 1979) and Belgium (c. 100 pairs in 1990, c. 400 in 1971); also declines in S Europe (Spain, Italy, Greece), but populations apparently still stable in E Europe (Hungary, Bulgaria, Romania, Russia). Threats include agricultural intensification (with generalized overfertilization leading to overgrown vegetation in wastelands and road margins), changes in urbanization practices (new housing or industrial areas now quickly forested), afforestation schemes and, possibly, climatic change. Reported as causing damage to agricultural crops during winter in Pakistan, where it attacks cultivated shoots of rape (*Brassica napus*) and chickpea (*Cicer arietinum*) plants, as well as sunflowers (*Helianthus*); also in Israel, where officially declared a pest species.

88. Thekla Lark

Galerida theklae

French: Cochevis de Thékla **German**: Theklalerche **Spanish**: Cogujada Montesina

Taxonomy. *Galerita Theklae* A. E. Brehm, 1857, Xàtiva, near Valencia, Spain.

Sometimes treated as forming a superspecies with *G. malabarica*, and has often been treated as conspecific, but proof of close relationship lacking. Marked geographical variation in colour, rather slight in size; variation strongly clinal in W of range, from grey-brown in N (Spain) to sandy-coloured in S (Sahara). Described race *aguirrei* (E Morocco) synonymized with *ruficolor*; birds named as race *deichleri* (Sahara of NE Algeria and SC Tunisia) considered to involve bleached individuals of *carolinae*. Genus name of original description based on unjustified (and indeed invalid) emendation of *Galerida*. Twelve subspecies currently recognized.

Subspecies and Distribution.

G. t. theklae A. E. Brehm, 1857 - E & S Portugal, Spain (including Balearic Is) and extreme S France (Roussillon).

G. t. erlangeri Hartert, 1904 - N Morocco (E to Algerian border, S to Middle Atlas).

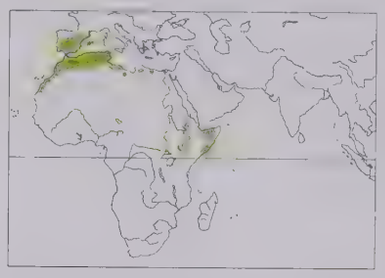
G. t. ruficolor Whitaker, 1898 - NE & C Morocco, coastal Algeria and N Tunisia.

G. t. theresae Meinertzhagen, 1939 - SW Morocco (S from Anti-Atlas Mts) and Western Sahara.

G. t. superflua Hartert, 1897 - Hauts Plateaux in NE Morocco (E of R Moulouya) and N Algeria (S to Atlas Saharien) E to Tunisia.

G. t. carolinae Erlanger, 1897 - N Sahara from extreme E Morocco (Figuig) E to NE Libya, probably also extreme NW Egypt (Salum).

G. t. praetermissa (Blanford, 1869) - highlands from S Eritrea S to C Ethiopia.



G. t. huei Érard & de Naurois, 1973 - SC Ethiopia (Bale Mts, Arussi).

G. t. huriensis Benson, 1947 - S Ethiopia and N Kenya (Huri Hills S to Marsabit).

G. t. ellioti Hartert, 1897 - N & C Somalia.

G. t. harrarensis Érard & Jarry, 1973 - E Ethiopia (Harar, Jijiga).

G. t. mallablensis Colston, 1982 - coastal S Somalia.

Descriptive notes. 15-17 cm; c. 30-40 g. Medium-sized, rather bulky lark with obvious crest, medium-length bill, rather short and broad-based wings with almost no primary projection, outer primary reduced (3 mm short of to 4 mm beyond tips of primary coverts), shortish tail, rather long (9-14 mm) straight hind claw. Nominate race has whitish supercilium and eyering, dark eyestripe and moustachial and malar stripes; crown and upperparts grey-brown, heavily streaked blackish, more finely so on hindneck, rump plainer, uppertail-coverts rufous-tinged; flight-feathers dark olive-brown, narrowly edged buffish to light cinnamon; tail olive-brown to greyish centrally, remainder black, except for pale rufous outer feathers; whitish below, breast side and flanks strongly tinged buff, lower throat to breast and breast side with well-defined large blackish spots (usually merging to form heavy streaks); axillaries and underwing-coverts greyish; bill dark horn-brown, paler base of lower mandible; legs flesh-brown to yellowish-flesh. Distinguished from very similar *G. cristata* by shorter and less decurved-looking bill (both mandibles convex), shorter and less spiky crest, usually better-defined breast streaking, greyer underwing, also marginally smaller and slimmer. Sexes similar. Juvenile has shorter crest, spotted upperparts, less intense chest streaking. Races differ mainly in coloration and in intensity of streaking, also in size and bill size: *erlangeri* is darker than nominate, streaking above and below broadest and blackest, bill longer; *ruficolor* is slightly paler than previous, feather edgings above more rufous, streaks below less intense; *theresae* resembles previous, but more rufous above, narrower streaks above and below; *superflua* is paler above, greyer or more sandy-coloured (variable), whiter below, upperparts and breast less streaked; *carolinae* is small and pale, light sandy to greyish with pinkish tinge above, plain or with minimal rufous streaking, mostly white below (sometimes pinkish wash), few scattered rufous-brown breast streaks, those in sandiest habitats often very pale and plain-looking ("*deichleri*"); *praetermissa* is small and dark, heavily black-streaked above, buffish below, breast spots relatively small and indistinct; *huei* is like previous but upperparts streaks heavier and blacker; *huriensis* differs from previous in paler upperparts, more distinctly streaked crown, whiter throat, pinkish belly; *ellioti* resembles last, but upperparts paler and more sandy rufous; *harrarensis* is darker than previous, broader streaks above and on breast, bill smaller; *mallablensis* is much greyer, lacks warm tones, upperparts feathers edged whitish to greyish or cold buffish, rump and tail-coverts grey, breast with relatively heavy dark brown spots. VOICE. Male song, mostly in flight or from top of bush, protracted series of whistles, twitters and warbling notes, very like that of *G. cristata* but perhaps more varied and joyful; often mimics songs of other bird species. Commonest call a fluty whistling of usually 3-4 notes, similar to that of *G. cristata* but more varied and energetic and with marked emphasis on final note.

Habitat. Rugged areas with shrubs and with high percentage of bare ground or semi-arid pasture; typically in hilly and broken landscapes, with rocky substrates. In Mediterranean Basin found in shrub-steppe and scrub of various botanic composition, often notably tall (1-1·5 m), but always with plenty of bare ground or short grass; also olive (*Olea*) and almond (*Prunus amygdalus*) groves and vineyards; usually avoids cereal cultivations. In dry streambeds with scattered oleander (*Nerium oleander*). Also arid or semi-arid steppic habitats or low acacia (*Acacia*) scrub in S of range. Common in lava desert in Kenya. At 50-2200 m, mostly below 1000 m; to 3200 m in S.

Food and Feeding. Mainly insects, also seeds, to lesser extent green plant material. Diet varies with season: mainly invertebrates in spring, mixed with seeds in early summer, and mainly seeds and plant shoots in summer-autumn. Very wide assortment of invertebrates and seeds recorded. Nestlings fed exclusively with invertebrates, mainly grasshoppers (Acrididae), spiders, caterpillars, mantids and beetles (Coleoptera), size range 12-21 mm, increasing through season. Forages on ground, singly or in pairs; outside breeding season also in family groups or small flocks of 5-10 individuals, occasionally up to c. 20, sometimes mixed with *Calandrella rufescens* or *Eremophila bilopha* in Africa, occasionally with *G. cristata*. Searches for items on ground, peers under stones. Breaks open snail shells by smashing them against rock or stone.

Breeding. Laying Feb-Jun (mostly from May) in N of range, from early Apr in N Africa but sometimes from Feb in W Morocco; in Somalia May-Jun in N, to Jul and once in Jan in S; May in E Africa; 1-2 broods, in Spain sometimes three. Monogamous, apparent pair-member fidelity during successive clutches, although extra-pair paternity recorded. Territorial. Male song usually from bushtop, sometimes in low flight, occasionally in high circling flight. Nest a depression on ground beside or beneath shrub or tuft, lined with grass stems, internal diameter 8-9 cm, earliest ones with small rampart of sticks, orientated mainly to NE-NW quarter. Clutch 3-5 eggs, rarely up to 7 (mode 4), in Spain no change in clutch size through season; incubation by female alone, beginning with last or penultimate egg, period 12 days; chicks cared for and fed by both sexes, leave nest at 9 days, sometimes later if nest not disturbed, fledging at 15 days. Breeding success often low; nest losses 80-90%. Interspecific nest parasitism recorded.

Movements. Resident. Sedentary in most of range, but some apparent longer dispersive movement or wandering in some areas. Occasional records in NW Mauritania presumably refer to vagrants.

Status and Conservation. Not globally threatened. Generally common or very common. In Europe, Iberian population estimated during early 1990s at 1,400,000-1,700,000 pairs, 94% of these in Spain, where widespread in all Mediterranean climate areas (most abundant in SE, i.e. Almería, Granada and Murcia provinces) and becoming progressively scarcer towards N & W; densities in favourable habitats 0·2-0·4 birds/ha, average maximum in best habitats c. 0·7 birds/ha. Recent declines in some areas of Spain attributed to irrigation and afforestation of steppic areas; at Las Amoladeras Reserve (Almería), sharp population decline due to increase in numbers of rabbits (*Oryctolagus cuniculus*) and foxes (*Vulpes vulpes*) following cessation of hunting. Tiny population in S France (Pyrénées-Orientales and Aude) numbers only 10-100 pairs. Common and widespread in most of N African range, and abundant in Western Sahara; probably commonest lark in Morocco (much more common than *G. cristata*), widespread in N Algeria (densities of 0·1-0·2 pairs/ha recorded), common in N Tunisia (numerous in some mountain areas), and in Libya locally common in Tripolitania and common in hills in Cyrenaica;

in Egypt probably breeds in extreme NW (Salum area), where recorded as common in 1920 and 4 males displaying in Mar 1994, but region seldom visited by ornithologists; possibly a very rare resident in NW Mauritania, where few records hitherto presumed to involve vagrants or wanderers. In E African range frequent in Ethiopia (W & SE Highlands and in S), and abundant and widespread in Somalia, where one of the commonest alaudids; locally common in N Kenya deserts E of L Turkana, and especially numerous in Dida Galgalu Desert.

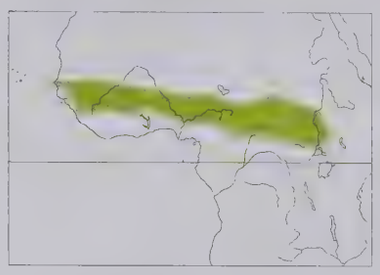
89. Malabar Lark

Galerida malabarica

French: Cochevis de Malabar **German**: Malabarlerche **Spanish**: Cogujada Malabar
Other common names: Malabar Crested Lark, Short-crested Lark

Taxonomy. *Alauda malabarica* Scopoli, 1786, China; error = Malabar coast, western India.
Sometimes treated as forming a superspecies with *G. theklae*, which often considered conspecific, but proof of close relationship lacking. Named race *propinqua*, known only from Londa district (Bombay), considered indistinguishable from other populations. Monotypic.
Distribution. SW India S from SE Gujarat.



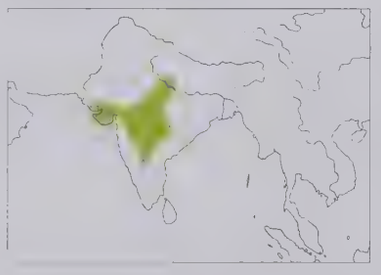
Descriptive notes. c. 16 cm. Medium-sized, fairly sturdy lark with prominent spiky crest (rather inconspicuous when folded), quite deep-based medium-long bill, fairly short tail. Has moderately distinct buffish supercilium, rather distinct dark loral stripe, and buffish or pale grey-brown ear-coverts with some darker streaking (mainly towards rear); crown and upperparts rufous-brown to more grey-brown, strongly streaked blackish-brown; upperwing-coverts and tertials dark grey-brown or blackish-brown with buffish tips and edges; remiges and tail dark grey-brown, penultimate rectrix with mostly rufous-buffish outer edge and sometimes tip of inner web, outermost rectrix with rufous-buff wedge of varying prominence on inner web; breast and flanks buff, breast with heavy blackish streaking, rest of underparts pale buffish or buffish-white, underwing extensively pale rufous; upper mandible mainly dark grey, lower mandible pale pinkish or slightly yellowish-tinged; legs pale pinkish. Distinguished from *G. cristata* (of race *chendoola*) by more rufous coloration and heavier streaking above, more buffish below, especially breast and flanks, deeper rufous-buff in outer tail, shorter and relatively deeper-based bill; from *G. deva* by larger size, less thick bill, paler and less uniformly coloured underparts with more profuse and usually heavier dark breast streaks. Sexes similar in plumage, female on average smaller than male. Juvenile has prominent whitish feather tips above, looking scaly or white-spotted. Voice. Song, in flight or, more commonly, from ground or low perch, comparatively slow, rich and varied, a mixture of different kinds of sounds, predominantly soft, piping, melancholy ones, including mimicry of other species; commonest call a quick series of 2-4 soft, piping, melancholy whistles. Vocalizations very similar to corresponding ones of *G. cristata*.
Habitat. Dry open habitats, preferably with some scrub and rocks, e.g. agricultural land, grass-covered stony hill sides and forest clearings; to 2000 m.
Food and Feeding. Diet poorly known; apparently seeds and invertebrates, e.g. orthopterans, beetles (Coleoptera), ants (Formicidae). Forages on ground, singly or in pairs; also in flocks of up to c. 30 individuals in non-breeding season.
Breeding. Breeds in all months, with possible exception of wettest ones (Jun-Jul). Song-flighting male hangs more or less still or flies about in irregular "circles" with relatively slow-flapping wings and partly spread tail. Nest a cup of grass and roots lined with finer material, in depression on ground, sheltered by stone or tuft of grass. Clutch 2-3 eggs; incubation and nestling periods not documented.
Movements. Sedentary or dispersive.
Status and Conservation. Not globally threatened. Locally fairly common to common. No estimates of population size or breeding densities.
Bibliography. Ali (1969), Ali & Ripley (1987), Alström *et al.* (2004), Dickinson & Dekker (2001a), Dickinson, Dekker, Eck & Somadikarta (2001), Grimmett *et al.* (1998), Koelz (1939), Pätzold (1994, 2003), Rasmussen & Anderton (2004), Ripley (1982), Stuart Baker (1926, 1935), Vaurie (1951a), Zacharias & Gaston (1999).

90. Sun Lark

Galerida modesta

French: Cochevis modeste **German**: Sonnenlerche **Spanish**: Cogujada Modesta

Taxonomy. *Galerida modesta* Heuglin, 1864, Bongo, Bahr-el-Ghazal, Sudan.
Has been considered to form a superspecies with *G. magnirostris*, also including *Pseudalaemon fremantlii* when that placed in present genus, but differences appear too great for such treatment to be warranted. Birds from Burkina Faso E to W Sudan named as race *giffardi* (often erroneously spelt as *giffordi*), but indistinguishable from nominate. Four subspecies recognized.
Subspecies and Distribution.
G. m. modesta Heuglin, 1864 - S Senegambia, S Mali and N Ivory Coast E to SW & S Sudan.
G. m. nigrita (Grote, 1920) - Guinea and N Sierra Leone.
G. m. struempelli (Reichenow, 1910) - highlands of N Cameroon.
G. m. bucolica (Hartlaub, 1887) - SE Central African Republic, NE DRCongo and extreme NW Uganda.



Descriptive notes. 14-15 cm; 18-22 g. Medium-sized, rather dark lark, heavily streaked above and on breast, with short erectile crest, rather small bill. Nominate race has creamy to buffish lores and supercilium, narrow dark eyestripe, brown ear-coverts, thin dark malar streak; crown and upperparts rufous to sandy rufous, blackish feather centres forming prominent streaks on crown, mantle and back, rump plainer and tinged cinnamon; wing-coverts blackish-brown with broad pale rufous margins, whitish tips; flight-feathers dark brown, narrowly edged rufous, tail blackish-brown, rufous edges of outer tail; throat whitish, breast buffy to pale rufous with heavy black streaking, belly and flanks slightly paler buff; underwing-coverts and axillaries rufous-buff; eyes dark brown; bill blackish-horn, whitish base of lower mandible; legs dark flesh-brown. Differs from *Mirafra rufocinnamomea* in slightly larger size, much more streaked plumage. Sexes alike. Juvenile has white feather tips above, appearing spotted, white margins of wing-coverts form two pale wingbars. Races differ primarily in plumage colour, tending to be paler in N, also in size: *bucolica* is darker than nominate; *struempelli* is larger than previous, also darker and more heavily black-streaked, with broader rufous edgings above; *nigrita* is smaller than last, darker and with narrower rufous edgings. Voice. Male song, in flight or sometimes from low perch, a series of sweetly whistled notes and buzzing sounds, often incorporating elements of songs of other birds, including bulbuls (Pycnonotidae) and swallows (Hirundinidae); also short, rather tuneless series of notes lasting 1-2 seconds, both from ground and in flight. Weak "chit-chit" when flushed.
Habitat. Open countryside, often rocky hills, where prefers areas of short grass and open rock; also occupies wide range of sparse grassy habitats, including fields and pastures. Often found on bare ground near villages and on sports fields.
Food and Feeding. Grass and other seeds, and insects. Forages on the ground, singly or in pairs; often in small flocks outside breeding season.
Breeding. Season Nov-Feb and May-Jul. Monogamous. Male sings in hovering aerial display. Nest built by female, accompanied by male, an open cup of grass and rootlets in shallow scrape on ground at base of a grass tuft, shrub or rock. Two clutches documented, each of 1 egg; nothing known about parental duties or incubation and fledging periods.
Movements. Resident in some areas; elsewhere, subject to more or less regular movements linked to seasonal rains, e.g. in Nigeria moves N in rains and S in dry season.
Status and Conservation. Not globally threatened. Locally common to not uncommon; very uncommon in extreme SE of range (NW Uganda). Adaptable; frequently occurs in agricultural lands and other human-modified habitats.
Bibliography. Bannerman (1953), Barlow *et al.* (1997), Borrow & Demey (2001), Byaruhanga *et al.* (2001), Chapin (1953), Cheke & Walsh (1996), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Érard & Morel (1994), Fishpool & Evans (2001), Grimes (1987), Jones (1991), Keith *et al.* (1992), Mackworth-Praed & Grant (1960, 1970), Nikolaus (1987), Salewski (1997b), Salvan (1968), Serle (1943), Short *et al.* (1990), Shuel (1938), Stevenson & Fanshawe (2002).

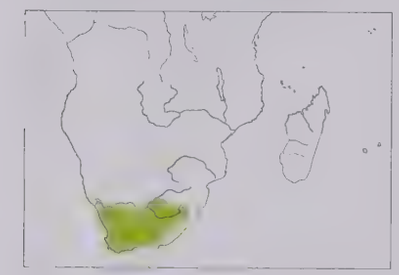
91. Sykes's Lark

Galerida deva

French: Cochevis de Sykes **German**: Devalerche **Spanish**: Cogujada de Deva
Other common names: Sykes's Crested Lark, Tawny/Deccan Lark

Taxonomy. *Alauda Deva* Sykes, 1832, Dukhun = Deccan, India.
Monotypic.
Distribution. WC & C India.

Descriptive notes. c. 14 cm. Quite small lark with prominent spiky crest (rather inconspicuous when folded), mostly buff plumage, medium-long stout bill, shortish tail. Has buffish supercilium, buffish ear-coverts with some dark streaking (mainly at rear), moderately distinct or indistinct dark loral stripe; crown and upperparts brownish-buff, heavily and contrastingly streaked blackish-brown, uppertail-coverts light rufous with little or no streaking; wings and tail blackish-brown or dark grey-brown, upperwing-coverts with buff fringes, penultimate rectrix with mostly warm buff outer edge and often tip of inner web, outermost tail feather with warm buff wedge on inner web; entire underparts warm buff or rufous-buff, breast with sparse thin dark streaks, mainly on sides, underwing extensively pale rufous; upper mandible mainly medium or dark grey, lower mandible pale pinkish; legs pale pinkish. Distinguished from *G. malabarica* by smaller size, deeper-based bill, paler, buffier and more contrastingly dark-streaked upperparts, deeper and more uniformly buff underparts, less profusely and more finely streaked breast. Sexes alike in plumage, female on average smaller than male. Juvenile differs in having prominent whitish feather tips above, giving scaly or white-spotted appearance. Voice. Male song, from ground or low perch or in flight, rich and varied, includes both harsh and clear notes, commonly with masterly imitations of other species, resembles songs of *G. cristata* and *G. malabarica* but fewer drawn-out whistles, more repetitions (phrases), more varied speed, harsher voice. Calls with various high-pitched, often multisyllabic, whistles and short guttural notes.
Habitat. Dry, stony areas with sparse scrubby vegetation, dry cultivation, and similar habitats; to c. 1000 m. Apparent preference for dark soils.
Food and Feeding. Diet poorly known; apparently seeds and invertebrates. Forages on ground, singly, in pairs or in small loose flocks; walks and runs; takes items mostly from ground surface.
Breeding. Little studied. Season at least Mar to Sept (probably more extensive), mainly May-Aug. Male performs high, sustained song flight with rather slowly flapping wings. Nest a small cup of grass and rootlets with finer lining, in scrape on ground, sheltered by stone or tuft of grass. Clutch 2-3 eggs, rarely 4; incubation and nestling periods not documented.
Movements. Sedentary; some short-distance dispersive movement.
Status and Conservation. Not globally threatened. Status uncertain; formerly probably fairly widespread and numerous, but now perhaps more local and less common. Relatively poorly known species.



Bibliography. Ali (1996), Ali & Ripley (1987), Alström *et al.* (2004), Dickinson & Dekker (2001a), Dickinson, Dekker, Eck & Somadikarta (2001), Grimmett *et al.* (1998), Mukherjee (1995), Pätzold (1994, 2003), Rasmussen & Anderton (2004), Ripley (1982), Stuart Baker (1926, 1935), Vaurie (1951a).

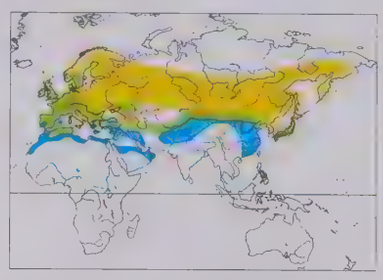
92. **Large-billed Lark**

Galerida magnirostris

French: Cochevis à gros bec **German**: Dickschnabellerche **Spanish**: Cogujada Picogorda
Other common names: (Southern) Thick-billed Lark(!)

Taxonomy. *Alauda magnirostris* Stephens, 1826, near Cape Town, South Africa.
Has sometimes been placed in a monotypic genus *Calendula*. Has been considered to form a superspecies with *G. modesta*, also including *Pseudalaemon fremantlii* when that placed in present genus, but differences appear too great for such treatment to be warranted. Geographical variation largely clinal, with clines of increasing body size and decreasing bill size from W to E. Birds from Lesotho sometimes separated as race *montivaga*, but probably better merged with *harei*. Three subspecies recognized.
Subspecies and Distribution.
G. m. sedentaria Clancey, 1993 - Karoo areas of extreme SW Namibia and W South Africa (E to Griqualand West).
G. m. magnirostris (Stephens, 1826) - winter rainfall area of SW South Africa.
G. m. harei (Roberts, 1924) - W grasslands of South Africa and Lesotho.

Descriptive notes. 18 cm; 35-48 g. Large, heavily built, straw-coloured lark with robust bill. Nominate race has fairly prominent creamy-buff to whitish supercilium, narrow dark eyestripe, faint dark moustachial line; crown and upperparts pale sandy brown, blackish-brown feather centres forming prominent streaks, rump less clearly streaked; wing-coverts dark brown with paler edges; flight-feathers and tail dark brown with buffish outer edges; whitish below, breast with dense heavy blackish-brown streaks, flanks with sparser narrow streaks, sometimes faint yellowish tinge on belly and undertail-coverts; underwing-coverts and axillaries light brown; eyes brown; bill dark horn-brown, obvious yellow base; legs pinkish-brown. Sexes alike. Juvenile has pale feather tips on upperparts, appearing pale-spotted above, white fringes of wing-coverts form two white wingbars, more buffy with diffuse rounded spots below, bill paler. Races differ in size, also in plumage tone: *sedentaria* is slightly more rufous above than nominate, wing and tail longer; *harei* has much smaller bill, plumage becomes slightly darker in E of range ("*montivaga*"). Voice. Typical song, in flight or from ground or perch, a fast, stereotyped, slightly wheezy "tit-it twiddle-iddle-eee" or "tit swee-ere-ee-ee", likened to sound of squeaky gate; in sustained song often mimics calls of other birds, single song bout of individual containing imitations of 13-20 species, including bustards (Otididae), cisticolas (*Cisticola*), coursers (Glareolidae), lapwings (*Vanellus*), longclaws (*Macronyx*), pipits (*Anthus*), sandgrouse (Pteroclidae), shrikes (Laniidae), sparrows (*Passer*) and starlings (Sturnidae), as well as other larks.
Habitat. Semi-arid grassland and dwarf shrubland, open coastal scrub, and fields. Most abundant in cereal cropland and pastures in Western Cape, as well as in montane grassland in Lesotho. Also common in open areas in Succulent Karoo; more local in grassy Nama Karoo, where found mostly along drainage lines and in bare areas.
Food and Feeding. Seeds of grasses, sedges, various forbs and legumes; also insects, including beetles (Coleoptera), caterpillars, cockroaches (Blattodea), termites (Isoptera) and ants. In the Karoo, grass seeds made up only 4% of all seeds consumed. Chicks fed mostly with insects. Feeds on the ground, singly or in pairs, rarely in small groups or family parties. Walks about, picks items from ground surface and bases of low plants; often uses robust bill for digging, excavates small bulbs, which then broken open and the flesh eaten. Also takes seeds directly from plants, and breaks open dung to obtain seeds and insect larvae. Regularly drinks water, especially in arid areas. Often perches on fence poles, less often on wires.
Breeding. Breeds chiefly during spring months Aug-Nov, occasionally later (in summer). Monogamous and territorial; pair-members remain together throughout year in most areas. Male performs laboured, dipping display flight up to 50 m above ground, lasting up to 5 minutes. Nest an open cup, varying in thickness, made of stems, grass leaves and rootlets, sometimes on foundation of sticks, and lined with wool or plant down, built in shallow scrape on ground, often at base of grass tuft, shrub or clump of earth; typically facing S or E in more arid areas. Clutch 2-4 eggs (mean 2·5); incubation period c. 16 days; chicks fed by both parents, at one nest 13 feeds per hour, faecal pellets removed by parents and carried at least 50 m from nest before being discarded; adults feign injury to distract intruders, may even fly up into face of human intruder; fledging period not known.
Movements. Largely resident; has been suggested that it undertakes some altitudinal movements in E of range, moving down from higher elevations in winter.
Status and Conservation. Not globally threatened. Generally common to very common. Has benefited from agriculture; abundant in cereal croplands in Western Cape. Also benefits from poor agricultural practices in the Karoo, often occurring only in areas where vegetation cover minimal as a result of overgrazing.
Bibliography. Broekhuysen (1963), Brooke (1985), Clancey (1993a), David (1971), Dean (1997), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Keith *et al.* (1992), MacGregor & Feely (1952), Mackworth-Praed & Grant (1962), Maclean (1974a, 1993a, 1999), Nuttall (2000), Quickelberge (1970b), Sinclair & Hockey (1996), Tarboton (2001).



Genus *ALAUDA* Linnaeus, 1758

93. **Eurasian Skylark**

Alauda arvensis

French: Alouette des champs **German**: Feldlerche **Spanish**: Alondra Común
Other common names: Skylark, Common/European/Northern Skylark; Japanese Skylark (*japonica*)

Taxonomy. *Alauda arvensis* Linnaeus, 1758, Europe = Sweden.
May form a superspecies with *A. gulgula*, and has been considered conspecific. Race *japonica* sometimes considered a race of that species owing to similarities in plumage and structure; alternatively, treated by many as a separate species on grounds of constant differences in plumage and apparent sympatric breeding with race *lonnbergi* of present species in Sakhalin, but limits of E taxa disputed by others; further study required. Large number of races described, but distributions and geographical boundaries poorly understood, obscured by considerable individual variation within populations, also by intergradation, and most taxa identifiable only by comparing series of specimens at same stage of plumage wear; validity of some generally accepted taxa remains questionable. Other proposed races sometimes recognized include *ticehursti* (NW Iberia), included in *guillelmi*; *dementieva* (SE of Caspian Sea), in *dulcivox*; *alticola* (SE Altai), in *kiborti*; *nigrescens* (Amur Basin), in *intermedia*; and *buxtoni* (NE coast of Sea of Okhotsk), in *pekinensis*. Thirteen subspecies tentatively recognized.
Subspecies and Distribution.
A. a. scotica Tschusi, 1903 - NW Europe (Faeroe Is, N & W Scotland, Ireland, NW England).
A. a. arvensis Linnaeus, 1758 - N, W & C Europe (E to W side of Urals).
A. a. guillelmi Witherby, 1921 - NW Spain and N Portugal.
A. a. sierrae Weigold, 1913 - S Portugal and C & S Spain.
A. a. cantarella Bonaparte, 1850 - S Europe from NE Spain E, including Mediterranean islands, to C & N Turkey and Caucasus.
A. a. harterti Whitaker, 1904 - NW Africa.
A. a. armenica Bogdanov, 1879 - SE Turkey and Transcaucasia E to N Iran.
A. a. dulcivox Hume, 1872 - breeds SE European Russia and W Siberia, S to N Kazakhstan, NW China (Xinjiang) and SW Mongolia.
A. a. intermedia Swinhoe, 1863 - breeds NC Siberia from basin of R Vilyuy and middle R Lena E to R Kolyma basin, S to NE China and Korea.
A. a. kiborti Zaliesski, 1917 - breeds Altai E to Transbaikalia, N & E Mongolia and NW Manchuria.
A. a. pekinensis Swinhoe, 1863 - breeds NE Siberia (from upper R Indigirka) E to Koryakland and S to Kamchatka and N Kuril Is.
A. a. lonnbergi Hachisuka, 1926 - breeds N Sakhalin, Shantar Is (in SW Sea of Okhotsk), possibly also lower Amur Basin.
A. a. japonica Temminck & Schlegel, 1848 - S Sakhalin, S Kurils, Japan and Ryukyu Is.
Introduced (*scotica*) in New Zealand and Australia; nominate in W Canada (Vancouver I); and both races in Hawaii.

Descriptive notes. 16-19 cm; male c. 35-50 g, female c. 26-40 g (*arvensis*). Medium-sized, fairly stout lark with shortish bill, fairly long wings with long primary projection (especially migratory races), relatively long tail, short erectile crest. Nominate race has whitish supercilium and eyering, contrasting dark ear-coverts, indistinct thin dark moustachial and malar stripes; crown and upperparts variably olive-brown to brownish-rufous (greyer in E of range), heavily streaked blackish, nape somewhat paler and less streaked; wing-coverts darker with broad pale fringes, but lesser coverts paler and more buffish; flight-feathers and tail dark brown to blackish with buffish edges, secondaries and inner primaries tipped white, outer rectrices white (prominent white trailing edge of inner wing and white tail side in flight); white to pale buff below, breast washed light rufous-buff and heavily streaked blackish, flanks with narrower streaks; bill pale horn; legs pale yellowish-brown to flesh-coloured. Distinguished from very similar *A. gulgula* mainly by larger size, longer primary projection, more buffish (less rufous) wing patch, in flight broad white trailing edge of wing and white (rather than buff) outer tail feathers. Sexes alike in plumage, female smaller than male. Juvenile has upperparts mottled buff and blackish with white edgings, breast more spotted than streaked. Races differ mainly in size and overall plumage tone (shades of grey, brown or rufous), but differences subtle, and following details only a general guide: *scotica* is like nominate but darker, more strongly streaked, more rufous-toned; *guillelmi* is dark and rufous like previous, but smaller; *sierrae* is paler and less heavily streaked than last, duller and browner; *cantarella* is paler than previous, somewhat paler than nominate and with narrower streaking; *harterti* has more sandy, less olive, appearance than last, longer and thinner bill; *armenica* is cinnamon-tinged with strong black streaks above (back more spotted), greyish when worn, breast with cinnamon ground colour, larger; *dulcivox* is rather distinctive, large, pinkish-buff above (greyish in worn plumage), streaks narrow and contrasting; *intermedia* is smaller and duller; *kiborti* resembles previous but slightly darker; *pekinensis* is larger and darker, dark rufous-brown and heavily streaked above, lesser coverts mostly dark rufous, breast rufous and well streaked; *lonnbergi* is also large and dark; *japonica* resembles previous two but slightly smaller, somewhat darker, dark breast contrasting with white throat and belly, flanks unstreaked. Voice. Male song, in flight, a prolonged, continuous rapid twittering interspersed with slower, generally ascending, phrases, contains variable amounts of mimicry, particularly of waders (Scolopacidae); more subdued version given from ground or perch. Commonest call a rich, rolling "prreet" or "chirrup", monosyllabic or disyllabic.
Habitat. Most open habitats. Strongly associated with farmland throughout much of range, but also occurs on heathland and moorland, meadows, grassland, steppe, edges of marshes, dunes, even extensive forest clearings; generally avoids wooded areas and xeric habitats, with taiga presenting a barrier in N across most of Eurasia, and S limit set by deserts and arid steppes. In Europe, highest densities in coastal marshes and certain types of low-intensity farmland, particularly set-aside and grazed hay meadows. Much variation in numbers in different types of farmland, generally commoner in arable habitats than in grass; cereals particularly important, and can support high proportion of individuals in some populations, although densities lower than in natural habitats. Avoids tall vegetation; absent from otherwise suitable habitats if surrounded by trees. In non-breeding season usually associated with arable land, particularly cereal stubbles, and coastal habitats, including beaches. Sea-level to c. 1000 m; locally higher, to 2750 m in Caucasus, and at 3500 m in S Spain (Sierra Nevada); to at least 3000 m in C Asia.
Food and Feeding. Small invertebrates and seeds, also other plant material. Primarily insectivorous in breeding season and vegetarian in winter. Nestling diet almost entirely invertebrates, predominantly insect larvae. Wide range of invertebrates taken, especially insect larvae, beetles (Coleoptera), grasshoppers (Acrididae), moths (Lepidoptera), spiders, flies (Diptera), less frequently worms (Oligochaeta), molluscs (Mollusca), aphids (Homoptera), mites (Acarina) and others. Unripe cereal grains may be important at certain times of year, particularly during rain. Spilt cereal grain a very important food source in winter; other food taken in winter includes leaves of cereals, grass and weeds, weed seeds and various invertebrates. Forages on the ground, singly or in pairs; outside breeding season in small groups or large flocks, sometimes of thousands of individuals. Walks and runs; foraging methods consist almost entirely of picking items from ground surface,

but digging, uprooting of plants, picking items from plants and kleptoparasitism all recorded. Does not drink water.

Breeding. Late Mar/early Apr to Aug-Sept in most of range, limits dependent on weather and habitat structure (often ceasing at harvesting in agricultural habitats); season probably shorter among migratory populations in Asia; up to four (rarely five) broods per season, fewer in N. Monogamous, male closely guards female prior to nesting; solitary, territorial, mean territory size in lowland farmland in Switzerland 2-8·3 ha (probably similar throughout W & C Europe). Male has characteristic song flight, rising diagonally into wind with tail spread, wings fluttering, to c. 100 m (occasionally higher, to 200 m), hovering for c. 1-10 minutes, sometimes longer (to 20 minutes, exceptionally up to 1 hour), then gliding downwards in spirals before sudden plummet to earth. Nest, built by female alone, a thick layer of grass, lined with finer vegetation, placed in excavated scrape or in natural depression on ground among short vegetation, sometimes more exposed; rarely, a rampart of small stones on outside; nests rarely abandoned, but birds about to nest will move to different site for nesting if habitat grows too tall or dense to allow easy access (e.g. winter-sown cereals). Clutch 1-7 eggs, usually 3-5, varying regionally, temporally and with habitat; in Europe mean clutch size increases from W to E, largest in Caucasus region (mean 4·8), also highest in middle of season, and higher in habitats with optimum food availability; incubation by female alone, from last egg, period 10-13 days; chicks fed by both parents, faecal sacs initially swallowed by parent, later removed and deposited away from nest; leave nest at 8-10 days (when legs fully developed), fledging at c. 16-20 days, sometimes later (24 days). Nest losses high, c. 70% on average; wide range of nest predators. First breeding at 1 year. Maximum longevity at least 10 years.

Movements. Resident and migratory. Populations in W & S Europe and across S & E limits of range in Asia predominantly resident, with some short-distance dispersive movement; also, some short movements to lower altitudes, and from grass-dominated to arable-dominated landscapes. Those in N & C Europe and across most of Asia migrate after breeding, moving mostly into areas occupied by residents but also to regions S of breeding range; populations breeding as far E as Urals Mts move W & SW in Sept-Oct to wintering grounds in S Britain, the Low Countries, France, Italy and Iberia, probably also N Africa (racial identity of winter visitors uncertain); farther E, migrants winter from Middle East E to N Indian Subcontinent, E China and Korea, although movements and distribution outside Europe poorly documented. Males tend to winter farther N than females. General climate warming has resulted in higher proportion of birds in C & N Europe remaining all year on breeding grounds in recent decades. Capable of long-distance flights over oceans, recorded from NC Pacific (Midway Atoll) in 1960s; other extralimital records from Iceland, Bear I, Azores, Madeira, Mauritania and, in E, Borneo; vagrants in SW USA (California) probably involve race *pekinensis*.

Status and Conservation. Not globally threatened. Generally widespread and common throughout range. One of the most widespread breeding species in Europe; total population estimated in 1980s and 1990s at approximately 33,500,000 pairs, of which c. 6,600,000 in Poland, 4,900,000 in Germany, 3,500,000 in Spain, 3,000,000 in European Russia, 2,200,000 in Bulgaria, 2,000,000 in United Kingdom, 1,500,000 in Belarus, 1,500,000 in Latvia, 1,200,000 in Czech Republic, 1,000,000 in Ukraine. No comparable figures for Asia, but common to very common in most parts; possibly the most abundant bird species across vast steppe areas of C Asia. Recent breeding records from W North America, on Pribilof Is (Alaska), probably involve race *pekinensis*. Although still very numerous, is currently listed by BirdLife International as a "Species of Conservation Concern in Europe", owing to massive declines, particularly in W Europe, since 1960s (mainly since mid-1980s); these exceed 50% in many countries, e.g. populations on lowland farmland in Britain declined by more than 54% from 1969 to 1991 (representing loss of c. 1,500,000 breeding pairs), and numbers in Germany reduced by 60% (with some local extinctions) and in Netherlands by at least 75%; declines largely a result of intensification of agriculture, and recent research indicates that changes in management of cereal-growing and grassland (leading to reduced nesting and foraging opportunities, and diminution of food resources) have been principal causes, although high hunting pressure in some countries poses additional threat. Densities in grassland and low-intensity farmland in 1950s and 1960s 100-200 pairs/km², now much lower. Trends outside Europe largely unknown. Introduced populations in New Zealand and Australia apparently stable, but those in Canada (Vancouver I) and on some Hawaiian islands declining rapidly.

Bibliography. 94. Oriental Skylark

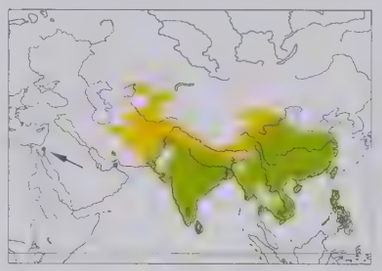
Alauda gulgula



French: Alouette gulgule **German**: Orientfeldlerche **Spanish**: Alondra Oriental
Other common names: Small/Lesser/Little Skylark, Eastern/Indian (Small) Skylark

Taxonomy. *Alauda Gulgula* Franklin, 1831, Ganges between Calcutta and Varanasi (Benares), east India.

May form a superspecies with *A. arvensis*, and has been considered conspecific. Race *japonica* of that species sometimes included within present species owing to similarities in plumage and structure. Geographical variation to some extent clinal, size decreasing from N to S. Other described races are *punjaubi* (from Pakistan and NW India) and *transcaspia* (Turkmenistan), merged with *inconspicua*; *dharmakumarsinhjii* (Gujarat, in WC India), *australis* (SW India) and *herberti* (C & SE Thailand E to S Vietnam), included in nominate; *sala* (Hainan), included in *coelivox*; and *wolfei* (Luzon, in Philippines), merged with *wattersi*. Eight subspecies recognized.

Subspecies and Distribution.

A. g. inconspicua Severtsov, 1873 - S Kazakhstan, S Uzbekistan, E Turkmenistan and E Iran E to W & SW Tadjikistan, Pakistan and NW India.
A. g. lhamarum R. Meinertzhagen & A. Meinertzhagen, 1926 - SW Pamir, extreme NE Afghanistan and W Himalayas (NE Pakistan S to N Punjab, E to Nepal).
A. g. gulgula Franklin, 1831 - NC & NE India S to Sri Lanka and E to Indochina.
A. g. inopinata Bianchi, 1904 - much of Tibetan Plateau, E Qinghai, Gansu (except most NW) and extreme SW Inner Mongolia.
A. g. vernayi Mayr, 1941 - E Himalayas and neighbouring parts of China (SE Xizang, W Yunnan).
A. g. weigoldi Hartert, 1922 - C & E China (SE Gansu and S Shaanxi S to S & E Sichuan, and E along Yangtse Valley).
A. g. coelivox Swinhoe, 1859 - SE & S China (including Hainan I) and N Vietnam.
A. g. wattersi Swinhoe, 1871 - Taiwan and Philippines.

Descriptive notes. c. 15·5-18 cm; 24-30 g (*inconspicua*). Small lark with medium-long and thin bill, fairly short tail, short primary projection, small erectile crest. Nominate race has fairly distinct buffish supercilium; crown and upperparts warm rufous-buff, heavily streaked blackish-brown; wings blackish-brown or dark grey-brown, upperwing-coverts and tertials with buff tips and edges, remiges with narrow rufous edges; tail blackish-brown, central feather pair with brownish edges, outermost pair light rufous-buff; light rufous-buff below, deepest on breast, blackish streaks on breast extending variably to flanks; bill pale pinkish with dark grey culmen; legs pale pinkish. Distinguished from *A. arvensis* by smaller size, shorter primary projection and tail, proportionately longer and more pointed bill, more buffish outer tail feathers, no distinct white trailing edge of wing in flight. Sexes alike in plumage, female on average smaller. Juvenile has distinct white feather fringes and dark subterminal bands above, extremely similar to juvenile *A. arvensis*. Races differ in size, relative bill length, coloration and strength of streaking: *inconspicua* is slightly larger than nominate, also palest and least streaked, ground colour above pale buffy grey-brown, whiter below, outer tail feathers buffish-white or pale buffish; *lhamarum* is slightly larger than previous, more rufous and more heavily streaked above, more rufous-tinged on breast, has white outer tail feathers; *inopinata* is largest, proportionately shortest-billed, somewhat intermediate between previous two in colour and strength of streaking above, whitest race below, has white outer tail feathers; *vernayi* resembles nominate above, but has rather whitish belly and white outer tail feathers, larger size; *coelivox* is proportionately longest-billed, similar to nominate in size and in colour and pattern above, but underparts paler, outer tail feathers off-white; *weigoldi* resembles previous but is larger; *wattersi* is less rufous and more heavily streaked above than last two, outer tail feathers pale rufous-buff. VOICE. Song, in flight, sometimes from perch or ground, a prolonged warbling and twittering with short whistles, very similar to that of *A. arvensis* but less varied, with more repetitions, and generally covers narrower frequency range. Commonest call a short explosive buzz, distinctly different from calls of *A. arvensis*; some other calls, especially in breeding season, more like those of latter species.

Habitat. Open habitats with short vegetation, e.g. grassland and cultivation, also saline coastal marshes and mudflats, dry edges of lakes, rivers and paddyfields, and semi-desert with *Tamarix* and *Haloxylon* bushes; found also in large forest clearings, but generally avoids closed, wooded or broken terrain. Lowlands and middle elevations; locally higher, to c. 4300 m in N Pakistan and N India. Generally replaces *A. arvensis* in E Palearctic and Oriental Regions, but occurs at higher altitude in some areas, also found more commonly in marshes, at wetland edges and in semi-desert.

Food and Feeding. Diet poorly studied; seeds and insects. Nestlings observed to be fed with moths and caterpillars (Lepidoptera) and with unidentified insect larvae. Ingests grit. Forages on ground, singly, in pairs or in loose flocks.

Breeding. Mainly Mar-Aug; chiefly Apr-Jun in most of India, but Nov-Apr/May in extreme S parts; mainly May-Aug in Himalayas and on Tibetan Plateau; often at least two broods. Male song flight at great height, hovering with quivering wingbeats for long periods, tail closed throughout. Nest a cup of grass, lined with finer grass, hair or rootlets, in depression on ground, generally sheltered by tuft of grass or mound of earth. Clutch 2-5 eggs, usually 3; incubation by female alone or, possibly, by both sexes, period 10-11 days; chicks fed by both parents, leave nest at c. 10 days, fledge a few days later.

Movements. Sedentary in most of range; some local, e.g. altitudinal, movements may be undertaken. Race *lhamarum* and C Asian populations of *inconspicua* mainly migratory, leave breeding areas between Sept and early Oct, return late Mar to mid-Apr or even, in case of former race, early May; wintering areas uncertain. Race *inopinata* partly migratory, known to occur in winter in e.g. Nepal, Bhutan, N Bangladesh, NE India and N Myanmar. Rare but regular winterer in some places in Israel and Arabia. Accidental in other places in Arabia, in NE Egypt (Sinai, several records) and in Iraq.

Status and Conservation. Not globally threatened. Common in most of range, locally abundant; uncommon in Philippines and locally in SE Asia. Has probably decreased substantially in much of C, S, SE & E China, presumably as a result of the disappearance of suitable habitats.

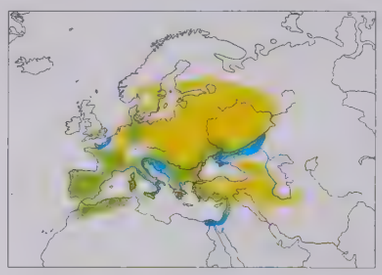
95. **Raso Lark**

Alauda razae

French: Alouette de Razo **German**: Rasolerche **Spanish**: Alondra de Razo
Other common names: Raso Short-toed Lark, Raso Skylark, Cape Verde Lark/Skylark, Raza Lark

Taxonomy. *Spizocorys razae* Alexander, 1898, Raso Island, Cape Verde Islands.
Previously placed variously in *Spizocorys*, *Calandrella* or a monotypic genus *Razocorys*. Behavioural traits, however, indicate that it is typical of present genus; recent genetic analyses suggest that it is very close to *A. arvensis*. Monotypic.
Distribution. Raso, in Cape Verde Is.

Descriptive notes. 12-13 cm; 18-28 g, male average 24 g, female average 20 g. Small lark with heavy, slightly decurved bill giving front-heavy appearance, relatively short wings (no obvious primary projection), short tail, small erectile crest, strong sexual size dimorphism. Has pale area around eye (sometimes slightly spectacled appearance), indistinct pale supercilium; greyish with dull dark streaks above; wings and tail darker, blackish, wing-coverts with pale tips, outer rectrix mostly white; throat white, rest of underparts pale creamy buff (whiter in worn plumage), breast streaked blackish; bill blue-grey, base of lower mandible whitish; legs dull flesh-coloured. Distinguished from *A. arvensis* by smaller size, longer and clearly larger bill, greyer plumage lacking rufous tones, in flight no white trailing edge of wing. Sexes alike in plumage; female significantly smaller than male in all measurements, wing average 80 mm (male 87 mm), bill 12·2 mm (male 14·6 mm). Bill length (especially of male) appears to vary seasonally, possibly through wear caused by digging. Juvenile has strong rufous tones, especially on ear-coverts and lower back, pale feather fringes above, breast markings more diffuse; very similar to juvenile *A. arvensis*. Voice. Male song, in flight or from ground, variations on a liquid "chirr-irr-ipp" or "chirru-dirru", given in bursts, with frequent intervals sometimes longer than song bursts, recalls that of *Galerida cristata*; simpler than song of *A. arvensis*, with more and longer gaps, but song during descent from flight faster, more complex and similar to latter's. Usual call "chirr-irr-ipp", like note of song flight.
Habitat. Found primarily on flat plain of decaying lava, mostly below 50 m. Strongly associated with dry streambeds (*ribeiras*) and scattered patches of sand, which support low vegetation after rain; also associated with grassy patches along tops of low cliffs on S coast of the island. Occasionally around rock pools at bottom of cliffs. In non-breeding season, a high proportion of population moves to a gravelly valley at E end of island.
Food and Feeding. Range of plant and insect species. In analyses of faecal samples of males during breeding season, all contained vegetable matter, c. 50% contained lepidopteran larvae. Other recorded items include seeds, beetles (Coleoptera) and marine gastropods; also takes discarded food scraps. Seen to chase small skinks (*Scincus*), although whether for food or to keep them away from nests is not known. Forages on ground. Much feeding involves use of the bill to excavate holes up to 10 cm deep in order to extract bulbs of the nutsedge *Cyperus bulbosus*; c. 3 minutes of digging required to yield one bulb, although dominant males increase the rate of food intake by displacing digging birds from holes, and in some places vigorously defend a number of holes; in sandy areas, ground sometimes littered with worked-out excavations. In gravel areas, feeds by pecking seeds or invertebrates from ground or from low vegetation, and by turning over small stones; also takes invertebrates, and scraps left by visiting fishermen, around rock pools. Males spend more time in digging than do females, possibly because of sexual differences in bill structure; difference between sexes in feeding strategy may have arisen as a means of partitioning resources in an austere environment. Occasionally drinks seawater from marine rock pools (no standing fresh water exists on Raso).
Breeding. Most nesting activity in Oct-Dec, following rainfall (which generally in Sept/Oct), but rain can fall at any time of year and nesting recorded in most months; conversely, long droughts can prevent breeding, sometimes for several successive years. Monogamous; male closely guards mate. Song-flighting male rises vertically to c. 30 m, hovers, descends steeply, singing throughout, display lasting on average 2 minutes, maximum 15 minutes in sample of 150, longest by unpaired males (which defend a territory, once two territories). Nest a deeply grass-lined scrape on ground, similar to that of *A. arvensis*, often under the low plant *Zygophyllum simplex*. Clutch 1-3 eggs; incubation by female alone, fed on nest by male, period at least 12 days; nestling period not documented; if nest preyed on, immediately begins a new one, sometimes using lining from original nest. Extremely high rate of nest predation, probably by the near-endemic gecko *Tarentola gigas*.
Movements. Resident; ranges widely during non-breeding season, although distances involved are small. No records away from Raso.
Status and Conservation. CRITICAL. Restricted-range species: present in Cape Verde Islands EBA. Has one of the smallest ranges of any bird species, confined to the single uninhabited island of Raso (7 km²), lying c. 20 km W of São Nicolau, in Cape Verde Is. May have been more widely distributed previously, when islands were joined together during periods of lower sea-level. The only lark on Raso. Total population extremely small, fluctuates in relation to rainfall, dropping to as few as ten pairs after prolonged droughts: in Oct 2001 estimated at c. 130 individuals, c. 66% of which males; total of 98 birds, only 30 of them females, in Jan 2003. Strongly male-dominated sex ratio perhaps explained by differences between males and females in feeding strategy. Despite the very small numbers, densities in favoured areas can be very high. Desertification is greatest threat to the species in the long term, as its population level is determined largely by rainfall. Potential introduction of cats or rats (*Rattus*) a further serious threat; although cats have been present on Raso in the past, and as recently as late 1990s, they do not appear to have established a breeding population. Development of tourist facilities on nearby São Nicolau and São Vicente is likely to result in increase in numbers of people visiting Raso, with resulting threats of disturbance, trampling and the accidental introduction of mammal predators. Raso is designated a national park, requiring visitors to apply for permission, although this rarely sought. The species is protected under Cape Verde law. Current conservation initiatives aim to increase capacity of Cape Verde authorities effectively to protect this lark and other important species in the archipelago.
Bibliography. Alexander (1898a, 1898b), Anon. (2003a, 2003c), Bannerman (1953), Borrow & Demey (2001), Bourne (1955, 1966), Burton (1971), Castell (1999), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Cramp (1988), Donald (2002), Donald *et al.* (2003), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Fraser (2004), García (1999), Green (1991), Hall (1963), van Harreveld (1985), den Hartog (1990), Hazevoet (1989a, 1995, 1999), King (1978/79), Ratcliffe *et al.* (1999), Stattersfield & Capper (2000).



Genus *LULLULA* Kaup, 1829

96. **Woodlark**

Lullula arborea

French: Alouette lulu **German**: Heidelerche **Spanish**: Alondra Totovía

Taxonomy. *Alauda arborea* Linnaeus, 1758, Sweden.
Genus possibly better merged with Alauda, as structural and behavioural differences between the two probably insufficient to justify splitting them. Yellow-tinged (fresh plumage) birds from Romania described as race *flavescens* and similar but marginally smaller ones from Crete as *wettsteini*, both regarded as indistinguishable from *pallida*. Two subspecies recognized.
Subspecies and Distribution.
L. a. arborea (Linnaeus, 1758) - breeds from S Fennoscandia, S Britain, France and N Iberia E to W Russia, Ukraine, N Italy and N Balkans.
L. a. pallida (Zarudny, 1902) - S Europe and NW Africa E (including larger Mediterranean islands) to Turkey, Caucasus, Levant (S to N Israel), Iran and SW Turkmenistan.

Descriptive notes. 15 cm; 23-35 g. Medium-sized lark with relatively slender bill, long-ish broad wings and short tail (looking dumpy in flight), short erectile crest, distinctive plumage markings. Nominate race has prominent white supercilia meeting to form V-shape on nape, rufous ear-coverts bordered white below, dark moustachial and malar stripes; crown and upperparts rufous-buff, prominently streaked black, rump browner and unstreaked, secondary wing-coverts and tertials browner with pale tips and edges; flight-feathers darker brown, primary coverts black with broad white tips, alula mostly whitish; tail with brownish central pair of feathers, remainder mostly blackish with broad white tips, outer rectrix dark brown with narrow pale brown outer edge; whitish below, washed buff on breast and flanks, breast streaked black, flanks with indistinct narrow greyish streaks; bill brown, pinkish base of lower mandible; legs flesh-coloured. Sexes alike, female slightly smaller than male. Juvenile has distinct pale feathers fringes above (scaly-looking), breast markings spot-like. Race *pallida* is paler and greyer than nominate, less buff below. Voice. Male song, in flight or from ground or perch, including at night, a clear, rich and melodious series of descending and clearly accelerating flourishes, "tlee tlee-tlee" notes soon turning into faster mellower "tlu" notes and followed by few whistles and warbling trill; slower and richer than songs of sympatric larks. Call a liquid "tee-luee" or "ti-tluee".
Habitat. Variety of open and semi-open habitats on well-drained soils, with preference for acidic sandy soils. Prefers unmanaged or poorly managed habitats such as low-intensity or abandoned farmland, heathland, young forestry plantations (particularly conifers up to 5 years old), recently felled woodland, open woodland and scrub, orchards, steppes, woodland edges and clearings, wooded coastal dunes and parkland; occurs rarely in more intensive agricultural areas, but no apparent competion with *Alauda arvensis* or other farmland larks. Requires bare ground or very sparse short vegetation for feeding, longer vegetation for nesting, and scattered perches. Sea-level to c. 2000 m; to 3000 m in NW Africa (High Atlas). Distribution closely related to warmer climates (more so than is the case with sympatric alaudids), primarily between 17°C and 31°C summer isotherms; areas with average minimum winter temperature below 1°C generally avoided.
Food and Feeding. Predominantly invertebrates during summer, vegetable matter in winter. Possibly more generally omnivorous throughout year than *Alauda* species; even in summer, adults consume considerable quantities of leaves and seeds of grasses and broadleaf plants. Chicks fed entirely with invertebrates, with lepidopteran caterpillars particularly important, and beetles (Coleoptera), flies (Diptera) and spiders also widely taken. Forages entirely on the ground, singly or in pairs; sometimes small groups in non-breeding season. Picks items from soil surface, also from low plants; relatively little digging. Brood-feeding adults forage mostly at average of c. 120 m from nest, but up to 400 m recorded.
Breeding. Mar-Jul, exceptionally to Aug; 2-3 broods. Monogamous; solitary and territorial. Male has well-developed butterfly-like song flight, climbs in spirals to c. 100-150 m, circles while rising and falling, or drifts in wide arcs, descends slowly, sometimes with final plummet, to perch or ground. Nest a deep depression in ground, usually beneath shade of a bush or tree stump, lined with leaves, pine needles and moss beneath top layer of finer grasses; often several scrapes dug by both sexes, but final nest built entirely by female. Clutch 2-6 eggs, normally 3-5; incubation by female alone, period 12-15 days; chicks fed by both parents, leave nest at 10-12 days, occasionally earlier if disturbed, fledge at c. 15-16 days; young remain in vicinity of parents during rearing of second brood, all forming small flock in autumn.
Movements. Resident, with short-distance dispersal, in W & S of range. Partial migrant in C Europe, migratory in N & E. Autumn passage across Europe mid-Oct to late Oct; ringing recoveries suggest that high proportion of N populations winter in SW France. Returning migrants reach Netherlands in late Feb, but not until Apr in Germany. Accidental in Faeroes, Ireland, Libya and Kuwait.
Status and Conservation. Not globally threatened. Fairly common; rather sparsely distributed, and often local. Total European population in 1990s estimated at between 900,000 and c. 3,000,000 pairs, and probably in the region of 1,500,000 pairs. Great majority of these in Spain (c. 850,000 pairs) and Portugal (at least 300,000), where average density c. 2·4 pairs/km²; densities far lower (c. 0·1-0·3 pairs/km²) in other countries, none of which regularly holds more than 50,000 pairs, and where the preferred heterogeneous habitats contain much vegetation that is too tall to be exploited for foraging. Apparent declines and range contractions recorded in some regions, and listed by BirdLife International as a "Species of Conservation Concern in Europe"; general tendency, however, for numbers to fluctuate quite markedly, and population levels partly dependent on winter weather, but habitat loss also a factor. Conversely, increases in the area of young coniferous forestry plantations, as well as creation of further suitable habitat in storm-felled mature woodland, have led to local increases and range expansion in some countries, especially in W Europe; successive mild winters in N, W & C Europe usually followed by marked rise in breeding numbers.

Class AVES

Order PASSERIFORMES

Suborder OSCINES

Family HIRUNDINIDAE (SWALLOWS AND MARTINS)

- Small to medium-sized aerial-feeding passerines, with long wings and streamlined body; tail forked in many species.
- 11-25 cm.

- Cosmopolitan.
- Wide variety of habitats, from semi-arid areas to forest, often near water.
- 19 genera, 83 species, 210 taxa.
- 5 species threatened; none extinct since 1600.

Systematics

Swallows and martins form a distinctive family, the 83 members of which are morphologically very similar to each other (see Morphological Aspects) and unlike all other passerines. This evolutionary conservatism is a result of the specialized lifestyle of the group, namely, the adaptations of swallows and martins to foraging on aerial insects, and it has made the establishing of relationships, both with other passerine groups and within the family, problematic. DNA-DNA hybridization studies, however, indicate that the closest relatives of the Hirundinidae are the Old World warbler-babbler group, including the sylviid warblers, the babblers (Timaliidae), the white-eyes (Zosteropidae), the tits and chickadees (Paridae), and the long-tailed tits (Aegithalidae), diverging some 50 million years ago. There is little fossil evidence of hirundinids, but a species known as *Hirundo aprica*, resembling the Barn Swallow (*Hirundo rustica*), was present 3·5-3·3 million years ago in North America.

Divisions within the family have long been uncertain, although two subfamilies are clearly recognized. The two species of river martin, forming the subfamily Pseudochelidoninae, are stocky swallows with a large syrinx and half bronchial rings; they seem to be relict species, occurring in Africa and South-East Asia, of a group that probably once had a much wider distribution. How closely related they are to each other is not clear. The White-eyed River Martin (*Pseudochelidon sirintarae*) has sometimes been placed in its own genus, *Eurochelidon*, but the differences between this species and the African River Martin (*Pseudochelidon eurystomina*), such as the former's longer and wider bill, are relatively minor.

All other members of the family are placed in the subfamily Hirundininae, the more typical elegant swallows and martins, which have more or less complete bronchial rings. In the past, many genera within this much larger subfamily have been created on the basis of generally small differences, such as the presence of feathers on the legs or the shape of the nostrils; these were often trivial and variable characters, however, and not helpful in indicating overall relationships. R. B. Sharpe and C. W. Wyatt, in their nineteenth-century monograph of the family, recognized twelve genera, but 26 had been created by the early twentieth century. In 1943, E. Mayr and J. Bond, in the first main treatment of the family, used nesting habits and colour patterns, as well as geography, to group many of these genera together. Some, however, have since been resurrected and further genera have been proposed. Recent DNA-DNA hybridization and cytochrome *b* studies of 17 species, undertaken by F. H. Sheldon and D. W. Winkler, have largely supported Mayr and Bond's approach, although these modern, molecular techniques have not resolved all of the relationships within the family and there is a clear need for more species to be examined. These studies do, however, indicate a division of the subfamily Hirundininae into three groups: the African saw-wings in the genus *Psalidoprocne*, a "core" martin group, and *Hirundo* and its allies. Nevertheless, despite these clear groupings of species, hirundines are very similar to each other genetically, especially when compared with some other groups, such as tits and chickadees, which have only a few

Subdivision of the Hirundinidae

[Figure: Hilary Burn]

All hirundines have aerodynamically efficient bodies, with a short neck, long, tapered wings and short legs. Tail structure varies and provides a rather loose division in terms of vernacular names. Species with short, squared-off or shallowly forked tails, such as the ***Grey-breasted Martin****, are known as martins, whilst those with deeply forked tails and, often, elongated outer tail feathers, such as the* ***Lesser Striped Swallow****, are known as swallows. There are, however, numerous exceptions!*

[Left: *Progne chalybea macrorhamphus*, Itatiaia National Park, Rio de Janeiro, Brazil. Photo: Edson Endrigo

Right: *Cecropis abyssinica unitatis*, Kruger National Park, South Africa. Photo: Heinri van den Berg/ Bios]

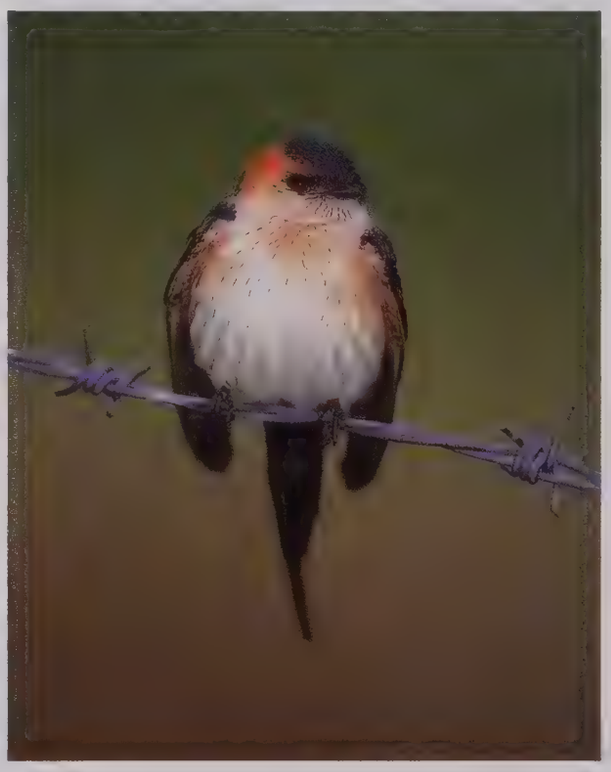
genera. They also have similar lifestyles, foraging and feeding in similar ways. The most notable differences among them with regard to ecology and behaviour are in nest type, in the size and swarming propensity of their prey, and in the degree of sociality while breeding.

The African saw-wings form a group of distinctive, dark-coloured glossy or brown swallows, all with a rough or "serrated" edge to the outer primary (see Morphological Aspects) and most having a deeply forked tail. Five species are generally recognized, four of which nest in burrows and one on ledges. It is typical of polytypic genera in the Hirundinidae for some of the species to be very similar to one or more of their congeners, and, accordingly, four of the saw-wings are treated as forming two superspecies. The saw-wing genus, however, is poorly known, and further work is required in order to sort out the relationships among the numerous forms. As is often the case in this family, the saw-wing races are not very distinctive, varying only slightly in shade of coloration, in size or in tail shape. Moreover, the non-breeding and breeding ranges are also little known, making it difficult to draw racial or species limits. Despite this, eight of the twelve subspecies of the Black Saw-wing (*Psalidoprocne pristoptera*) have often been treated as full species, as there are areas of range overlap within which apparently little interbreeding occurs.

The core martin group includes a large number of diverse taxa. The small Grey-rumped Swallow (*Pseudhirundo griseopyga*) of Africa, once included in the genus *Hirundo* because of its coloration, is closely related to the White-backed Swallow (*Cheramoeca leucosterna*) of Australia, but is a sister-taxon to the other members of the core martin group. Both species have a deeply forked tail and both nest in burrows. The genus *Phedina* also has a disjunct distribution, comprising two martins with brown upperparts, striped underparts and a square tail, one breeding in Madagascar and the Mascarene Islands and the other in the lower Congo Basin. The nesting habits of the two differ, however, the Mascarene Martin (*Phedina borbonica*) building an open cup of plant material and Brazza's Martin (*Phedina brazzae*) using burrows, and the latter has sometimes, therefore, been placed in a monotypic genus, *Phedinopsis*. The brown-and-white sand martins in the genus *Riparia*, which excavate nesting burrows, are more widespread, with four species in the Old World and one, the Collared Sand Martin (*Riparia riparia*), in both the New and the Old Worlds. As is common among the Hirundinidae, the variation among the sand martins in such characters as size and coloration is slight and mainly clinal, with subspecies grading into one another, making not only racial distinctions but also those between races and species difficult. Until recently, all sand martins in Eurasia were treated as representing one species, but two population types that differ in both appearance and voice have been found breeding sympatrically, and these are now considered to be separate species, the Collared Sand Martin and the Pale Sand Martin (*Riparia diluta*). The Banded Martin (*Riparia cincta*) of Africa stands out from the rest of this group in being larger, with a squarer tail and a more solitary lifestyle. It has sometimes been placed in its own genus, *Neophedina*, but cytochrome *b* data suggest that *riparia* and *cincta* are, indeed, sister-taxa.

In contrast, all of the remaining members of the core martin group are found only in the New World and all use existing cavities as nest-sites. Their relationships, however, are poorly known, as are, in many cases, details of their biology. The nine species of *Tachycineta* are glossy blue-backed or green-backed swallows with white underparts. A century ago, R. Ridgway divided them among four genera, whereas, 70 years later, R. K. Brooke proposed a single genus with two subgenera. More recently, comparison of DNA sequences also suggests a single genus, with two clades corresponding to these subgenera. One clade is a distinctive group of five white-rumped species which replace each other geographically from north to south in Central and South America. These are the Mangrove Swallow (*Tachycineta albilinea*), the Tumbes Swallow (*Tachycineta stolzmanni*), the White-winged Swallow (*Tachycineta albiventer*), the White-rumped Swallow (*Tachycineta leucorrhoa*) and the Chilean Swallow (*Tachycineta meyeni*). The first three and the last two, respectively, are considered to form two superspecies. The other clade consists of two North American species, the Tree Swallow (*Tachycineta bicolor*) and the Violet-green Swallow (*Tachycineta thalassina*), and two from the Caribbean, the Golden (*Tachycineta euchrysea*) and the Bahama Swallows (*Tachycineta cyaneoviridis*); the Violet-green Swallow is closest to the last two, despite their geographical separation, with the Tree Swallow a sister-taxon to them.

Where populations are geographically isolated, it is sometimes not clear whether they represent races of a particular species



Barn Swallows *demonstrate many of the features that make the family such successful aerial hunters. The wings are long in relation to their area and their ratio of body weight to wing area is low, these features allowing exceptional manoeuvrability at low speeds. Such a wing shape also allows for frequent bouts of gliding whilst foraging, reducing energy demands and boosting efficiency. Equally important is the forked tail which provides lift and plays a key role in manoeuvring, in rate of climb, and in acceleration. Wing and tail shape are adapted to suit the flying style of individual species, and this in turn reflects their prey preferences. The forked tail of this species allows for very tight turns during the pursuit of prey.*

[*Hirundo rustica rustica*, Norwich, England. Photo: Tony Tilford]

or constitute separate species. This is a recurring difficulty in the Hirundinidae, many forms of which are too poorly known for their taxonomic status to be resolved. The Mangrove Swallow is a good illustration of the problem. It occurs in Middle America to as far south as Panama, but a century ago a population in Peru and Ecuador was described as a subspecies of it, apparently differing in small respects such as lacking a white supraloral streak, having greyer underparts and being slightly smaller. The large geographical distance between the two forms would suggest that they are distinct species, but only recently has evidence in support of this come to light. On the basis of nest structure, vocalizations, morphology and cytochrome *b* data, the South American form is now treated as a species in its own right, the Tumbes Swallow.

The relationships of the various species and subspecies of the large *Progne* martins are still uncertain and require further work. The 14 taxa are similar in morphology and behaviour, and they are difficult to distinguish in the field. Several forms are regarded variously as subspecies or as full species by different authors. The Cuban (*Progne cryptoleuca*) and the Sinaloa Martins (*Progne sinaloae*), for example, are sometimes treated as full species, sometimes as races of the Caribbean Martin (*Progne dominicensis*) and sometimes as races of the Purple Martin (*Progne subis*). Likewise, the Galapagos Martin (*Progne modesta*), the Peruvian Martin (*Progne murphyi*) and the Southern Martin (*Progne elegans*) have been considered conspecific by many authors. Of the nine species currently recognized, eight are thought to form a superspecies. The ninth species, the Brown-chested Martin (*Progne tapera*), differs from the others in having brown, rather than blue, plumage, a slender bill, weaker feet, a less deeply forked tail, and greater feathering on the tarsus, as well as in the fact that the sexes are alike. Because of these differences it is often placed in a separate, monotypic genus, *Phaeoprogne*, but DNA-DNA hybridization and cytochrome *b* data suggest a particularly close relationship with the Grey-breasted Martin (*Progne chalybea*).

The genera *Notiochelidon* and *Haplochelidon* are closely related to *Atticora* and *Neochelidon*, which are also sister-taxa. The four species of *Notiochelidon* are blue-and-white or brown-and-white montane swallows, occurring at different altitudes; two of them, the Blue-and-white Swallow (*Notiochelidon cyanoleuca*) and the Pale-footed Swallow (*Notiochelidon flavipes*), are often put in a separate genus, *Pygochelidon*. Now treated in a monotypic genus, the Andean Swallow (*Haplochelidon andecola*) was for a long time thought to be a type of cliff swallow (*Petrochelidon*/*Hirundo*), although its plumage coloration differs in lacking red, and it does not build a mud nest; DNA-DNA hybridization studies, however, strongly indicate that it belongs in the core martin group along with *Notiochelidon*, *Atticora* and *Neochelidon*. The two species of *Atticora* are glossy blue-black and white, with a long forked tail, and occur along rivers in South America, while the closely related White-thighed Swallow (*Neochelidon tibialis*),

Red-rumped Swallows *frequently perch, which can facilitate close examination of their typically weak feet. Despite their feet being primarily adapted for perching, many hirundines are also at home on the ground, which they mostly visit to collect nesting material, grit and, occasionally, insects. In the subfamily Hirundininae, which includes the Red-rumped Swallow and the vast majority of the hirundines, the legs are typically short and weakly muscled. This shared trait, along with many other examples, reflects the unusual level of genetic similarity across the subfamily.*

[*Cecropis daurica rufula*, Lesbos, Greece. Photo: David Tipling/ Windrush]

Tail morphology generally relates directly to hunting technique and prey type, and in some species it also plays a part in mate selection. For some species with elongated outer tail feathers, or streamers, it has been shown that tail length operates as a visible indicator of breeding fitness: males with longer tails are more attractive to females. It is tempting to speculate that in the ***Wire-tailed Swallow*** *the primary function of the very thin filaments of the outer tail feathers is to telegraph this sexual message, as the rest of the tail is rather short and square-cut. Streamers are usually present in species with longer, more forked tails, clearly related to aerodynamics.*

[*Hirundo smithii filifera*, Keoladeo Ghana National Park, India. Photo: Manfred Pfefferle]

another brownish South American hirundinid, is the sole member of its genus.

Concluding the core martin group are three rather drab brownish swallows with a more or less square tail which nest in burrows. The rough-wings (*Stelgidopteryx*) were initially considered to consist of several species, but were later regarded as constituting just one species with many races. As with the sand martins in the genus *Riparia*, variation in characters tends to be clinal. The discovery of two different populations of rough-wings breeding in the same area in Central America, however, led to the conclusion that there were two separate species, the Southern Rough-winged Swallow (*Stelgidopteryx ruficollis*) and the Northern Rough-winged Swallow (*Stelgidopteryx serripennis*). The monotypic Neotropical genus *Alopochelidon* is sometimes merged with *Stelgidopteryx*, but the Tawny-headed Swallow (*Alopochelidon fucata*) lacks the latter's "serrated" edge of the outer primary.

Hirundo and its allies, the last of the three groups of the Hirundininae, comprises the species that build mud nests. Many have glossy blue upperparts, with red on the head, rump or underparts, and white patches in the often forked tail. DNA-DNA hybridization studies and cytochrome *b* data have indicated that *Hirundo* and *Ptyonoprogne* are sister-taxa and that *Delichon*, *Cecropis* and *Petrochelidon* are monophyletic, with *Cecropis* being close to *Petrochelidon*. The two last-mentioned genera, as well as *Ptyonoprogne*, have often been subsumed in the genus *Hirundo*, and a merging of *Delichon* with *Hirundo* has also been suggested, but Sheldon and Winkler's studies support the retention of, at least, *Delichon*, *Cecropis* and *Petrochelidon*. That all the mud-nest builders are closely related is reflected in the occurrence of hybridization between species of different genera, with hybrids between Barn Swallows and Northern House Martins (*Delichon urbicum*) and between Barn Swallows and Cave Swallows (*Petrochelidon fulva*) being particularly frequent. Nevertheless, each of the five genera within the *Hirundo* clade comprises a distinctive group of swallows.

With a total of 14 species, all of which build open cup-nests, *Hirundo* is the largest genus in the family. This genus can be further divided into several natural groups. The seven species of the "barn swallow group" have glossy blue upperparts, pale underparts, and rufous on the forehead and, often, on the throat. They are mostly African, but the Welcome Swallow (*Hirundo neoxena*) occurs in Australasia and the Pacific Swallow (*Hirundo tahitica*) from south Asia eastwards to the South Pacific islands, while the Barn Swallow itself breeds right across the Northern Hemisphere and has recently been found nesting also south of the equator, in Argentina. The Welcome and Pacific Swallows are often treated as conspecific. Even in the case of the Barn Swallow, probably one of the best-known bird species in the world, relationships between the various subspecies are not yet understood. Further work is needed, in particular to assess whether the North American and the Eurasian forms, which differ, for example, in incubation behaviour, as well as genetically, constitute separate species. Apart from the Wire-tailed Swallow (*Hirundo smithii*), which is found in Africa and Asia, the remaining *Hirundo* species are all restricted to the Afrotropical Region. Among these, two distinctive groups are comprised by, respectively, the Pied-winged (*Hirundo leucosoma*), White-tailed (*Hirundo megaensis*) and Pearl-breasted Swallows (*Hirundo dimidiata*), which lack any rufous coloration, and the Montane Blue (*Hirundo atrocaerulea*) and Black-and-rufous Swallows (*Hirundo nigrorufa*), both of which build their nests with mud and plant material combined, rather than using mud alone (see Breeding).

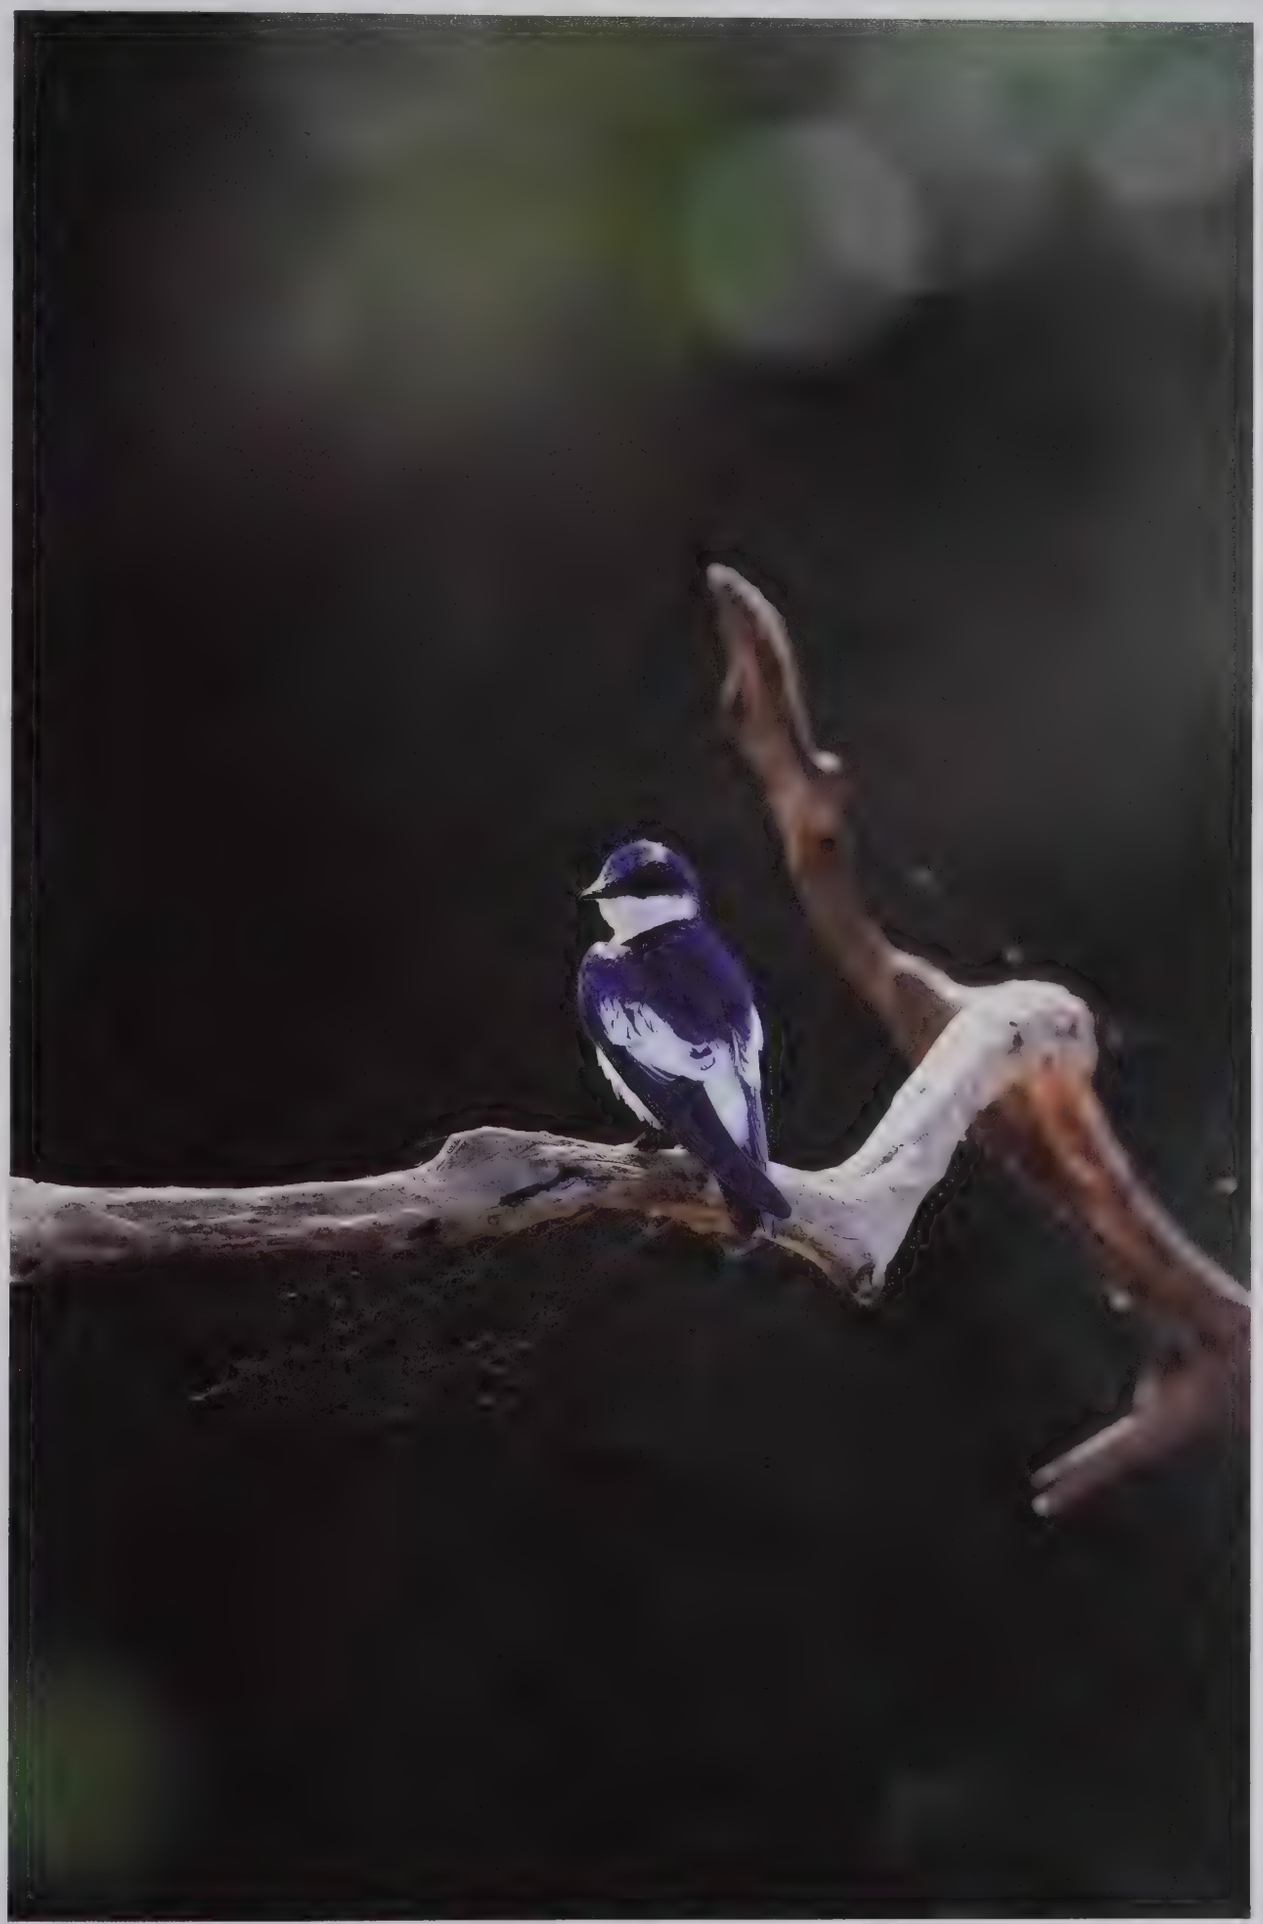
The three crag martins (*Ptyonoprogne*) form a group of dull brown, montane hirundines which, like the *Hirundo* swallows, construct an open cup-nest. One species occurs in southern Europe, North Africa and Asia, another is found in Africa, the Middle East and south-west Asia, and the third is resident in southern Asia alone. They provide a further example of the difficulty of determining the level at which various taxa in this family should be treated. The northern races of the Rock Martin (*Ptyonoprogne fuligula*) are often considered as constituting a separate species under the name "*Ptyonoprogne obsoleta*", usually referred to as the Pale Crag Martin, but the variation in coloration and size among the Rock Martin's 13 subspecies is largely clinal and the races intergrade with one another. Further, all three currently recognized species of *Ptyonoprogne* have been treated as conspecific by some authors, but, as their breeding ranges overlap, this proposition is unlikely to be tenable.

Breeding in Europe and Asia are three rather distinctive hirundines, the house martins (*Delichon*), which are blue and

white and have a squarish tail. The house martins build an enclosed nest, while the swallows in the genera *Cecropis* and *Petrochelidon* go further in adding a tunnel. *Cecropis* is represented by four African species, two more in south-eastern Asia and one in Europe, Africa and Asia. These exhibit considerable amounts of rufous in the plumage, mostly on the head, neck and rump, often combined with streaking on the underparts, and have a deeply forked tail. The most widespread of the seven species, the Red-rumped Swallow (*Cecropis daurica*), forms a superspecies with the two solely Asian ones, which have often been treated as conspecific; indeed, all three have sometimes been considered to represent just a single species.

The final genus in the family, *Petrochelidon*, is more cosmopolitan, with five species in the Afrotropics, three in the Americas, one in India and two in Australia. Apart from the wholly brown-plumaged Forest Swallow (*Petrochelidon fuliginosa*), they, too, have rufous or buffy coloration on the head and rump, but they have a square-ended or only shallowly forked tail. It is possible, however, that two of the eleven species do not belong to this group. The Forest Swallow differs from the others not only in its general coloration, but also in its bill shape, its solitary nesting habits, the shape of its nest, and its usually unspotted, white eggs, although these characteristics may be adaptations to its forest environment. Similarly, the Tree Martin (*Petrochelidon nigricans*) differs from typical *Petrochelidon* species in, for example, the fact that it does not build an enclosed mud nest with a tunnel. Further research may demonstrate that both the Forest Swallow and the Tree Martin should be placed elsewhere, either in other existing genera or, possibly, in new, monotypic genera. The taxonomy of this genus at the subspecific level has also proved to be complex. Until recently, the Cave Swallow was generally treated as comprising two main populations which were widely separated geographically, one breeding in the southern United States, Mexico and the Caribbean, and the other resident in south-west Ecuador and west Peru. As demonstrated in 2000 by J. J. Kirchman and co-workers, however, cytochrome *b* data suggest that two species are involved, the Cave Swallow in the north and the Chestnut-collared Swallow (*Petrochelidon rufocollaris*) in the Neotropics. In addition, the northern population, the Cave Swallow, appears to be represented by two clades, forming eastern and western populations. Clearly, more research is required in order to determine the best way of treating this group of taxa.

Mayr and Bond, in their 1943 treatment, considered that cavity-nesters were the most primitive hirundines, but the recent DNA studies, in contrast, indicate that, for this family, excavation of a hole is the ancestral way of creating a nest, occurring among the African saw-wings and some of the core martin group, such as *Pseudhirundo*, *Cheramoeca* and *Riparia*, as well as in the river martins in the subfamily Pseudochelidoninae and among the related family Paridae. Species that use holes and those that make nests of mud may be derived independently from nest-excavators. The strategy of taking over an old hole or nest as a nesting option seems to have arisen independently several times among hirundines. The majority of the martin group use pre-existing holes, whereas *Hirundo* and allied species make nests from mud. Even so, some burrowing and mud-building species occasionally nest in old holes or nests, and the Mountain Saw-wing (*Psalidoprocne fuliginosa*), the Mascarene Martin and the Tree Martin, all members of typically burrowing or mud-building genera, usually do so. In addition, the Black Saw-wing will sometimes use a pre-existing hole, perhaps just enlarging it, and Mosque Swallows (*Cecropis senegalensis*) sometimes take over nests of other swallows, build them up and add a tunnel entrance. In contrast to hole-nesting, both burrowing and mud-nesting appear to have evolved only once, with different species making the burrow or nest in basically similar ways (see Breeding). Burrowing arose early in the evolution of the family, whereas mud-nest building developed relatively recently with the *Hirundo* clade; the method of construction of pure mud nests by this latter group is unique among birds. As intimated above, there are three types of mud nest, of which the open cup-nest of *Hirundo* itself and of *Ptyonoprogne* is likely to be the most primitive. In the second type, that of the three *Delichon* species, the walls of the nest are built up so as to close the structure, leaving just a small entrance hole. The third type of mud nest, the retort-shaped nest with tunnel entrance constructed by *Cecropis* and *Petrochelidon*, is probably the most recently evolved.



Morphological Aspects

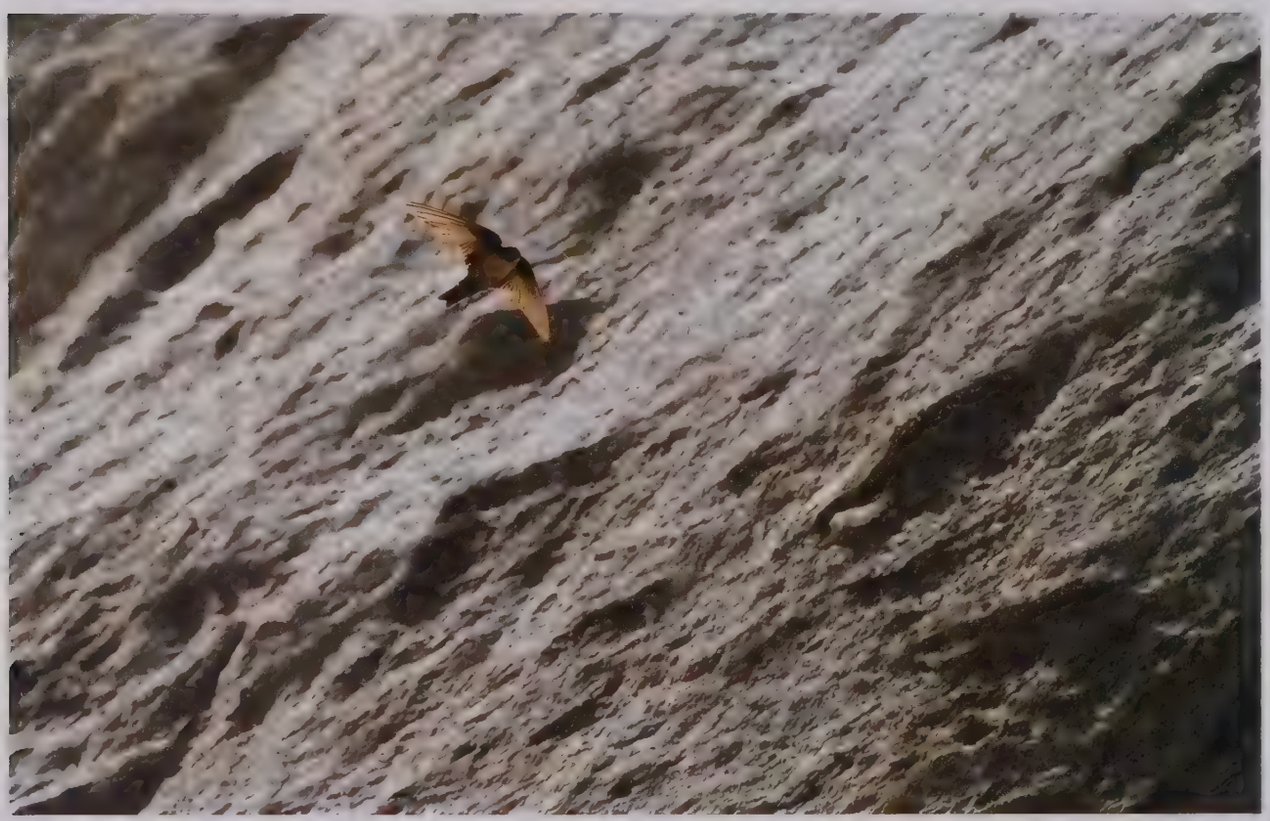
Hirundinids are small to medium-sized passerines. The smallest, such as the White-thighed Swallow, weigh about 10 g and the largest New World martins over 60 g. They are all specialist aerial insectivores, foraging by pursuing insects in flight, and they are superbly adapted to this way of life. The various species in the subfamily Hirundininae have a streamlined body with a short neck, long, pointed wings, short legs with small, weak feet, and reduced leg muscles compared with other passerines; they also possess a short, broad bill. Many have a forked tail, and on some species the outermost tail feathers are elongated and narrowed to form streamers. Incidentally, the hirundines with a square-ended or shallowly forked tail are often referred to as martins, and those with an elongated tail as swallows, but there is no hard and fast rule in these designations; *Riparia riparia*, for example, is commonly known as the "Bank Swallow" in the Americas and as the

*The **Welcome Swallow** has a plumage pattern typical of a number of hirundines. Most show dark upperparts and pale underparts, and many have a striking pale or rufous forehead, throat, breastband and, occasionally, rump. Sexual dimorphism is not marked in hirundines, females tending to be slightly duller than males and, in species with tail streamers, to have shorter tails.*

[*Hirundo neoxena*, Australia.
Photo: Cyril Ruoso/Bios]

The distribution of the ***White-winged Swallow*** *is closely tied to open areas in close proximity to favoured wetland habitats in the lowlands, and the species is often observed perched on dead snags over rivers and along the margins of lakes and reservoirs. It also frequents mangroves, beaches and seasonally flooded grassland and savanna. Hirundines have evolved to occupy most of the naturally occurring open and semi-open habitats around the globe and they also use a large proportion of man-made habitats. Wetland species, such as the White-winged Swallow, readily forage over sewage works and wet pastures but other species such as the Barn Swallow* (Hirundo rustica) *are even able to forage and breed in busy urban environments. Hirundine breeding habitats require a plentiful supply of two things: prey and suitable nest-sites. Nest-site requirements differ throughout the family. Some species, such as the* Tachycineta *swallows, utilize natural or artificial cavities, and to a certain extent their distribution and population numbers are dictated by the availability of suitable nest-sites. The remaining species avoid this potential limitation by constructing their own nesting cavities of mud or excavating their own burrows. Such nests are situated on a variety of substrates from natural examples, such as cliffs and riverbanks, to man-made habitats, such as bridges and buildings. It is those hirundines that build mud-nests, notably the very successful Barn Swallow, that are most closely associated with human habitation.*

[*Tachycineta albiventer*, Aquidauana, Mato Grosso do Sul, Brazil. Photo: Edson Endrigo]



*The **Mosque Swallow** is found virtually throughout sub-Saharan Africa, where it occupies a variety of open and semi-open habitats including cultivated areas, riparian corridors, forest clearings, woodland, bush, grassland and, to a lesser extent, areas close to human habitation. Mosque Swallows invariably build a mud-nest but also occasionally modify an existing cavity or repair old nests. No doubt, this flexibility regarding nest-site selection, associated with the species's broad range of foraging habitats, explains its large, and expanding, geographical range. The genus* Cecropis *is often lumped into* Hirundo *but recent genetic research supports their separation.*

[*Cecropis senegalensis saturatior*, Ethiopia. Photo: Roland Seitre]

Collared Sand Martin elsewhere. The tail has twelve rectrices. The loral feathers are directed forwards, and some species have rictal bristles. The wings have ten primaries, the outermost being reduced. The tarsi are short, with a ridged rear surface; the toes and tarsi sometimes have feathers, and the front toes are more or less united at the base. The bill, the eyes and the legs and feet are generally dark brown or black. Internally, the syrinx has more or less complete bronchial rings. The palate is broad, and the tongue tapers to a bifid tip.

The two river martins that make up the subfamily Pseudochelidoninae are more stocky, with a relatively large yellow or orange-red bill and robust, pinkish legs and feet. They have a large syrinx with half bronchial rings and a large membrane the length of the bronchial tubes. Their leg muscles are also less reduced than those of the Hirundininae.

In flight, the long wings are characteristic of this family, although they resemble the more sickle-shaped wings of the convergent swifts (Apodidae). The high aspect ratio, with long wing-

*The **Eurasian Crag Martin** is found throughout the Palearctic, where it breeds mainly in mountainous regions and forages along cliff faces and other rocky areas, and occasionally over adjacent habitats. It is found from sea-level to over 4000 metres but mostly occurs in medium-altitude alpine valleys. This species forages by exploiting updraughts along cliff faces, flying close to them and snatching flushed insects. Recently the species has started to utilize man-made structures for nesting, and this has allowed a spread into the lowlands. During the winter, birds migrate or drop in altitude to make use of a wider range of lowland habitats including farmland, meadows, rocky coasts and wetlands.*

[*Ptyonoprogne rupestris*, Turkey. Photo: Lasse J. Laine/ Windrush]

*Not all hirundines have broad ecological requirements that allow them to make use of a wide range of habitats. Some are extremely specialized, like the poorly known **White-banded Swallow**, which is restricted to the upper reaches of forested lowland rivers in northern South America. This species forages low over the water and occasionally over the adjacent forest, and it may avoid competition with sympatric hirundines by feeding much closer to the surface of the water or vegetation. Nests are situated in holes and burrows in the riverbanks; it is not known whether this species is capable of excavating its own burrow or simply relies on taking over those of other species.*

[*Atticora fasciata*, Alta Floresta, Mato Grosso, Brazil. Photo: Edson Endrigo]

span in relation to wing area, and the low ratio of body weight to wing area (low wing-loading) allow the swallows and martins to fly slowly when turning to catch insects. The wing shape is also advantageous for gliding, an energetically inexpensive method of flying and one frequently practised by hirundines. Together, these features explain the relatively low flight costs of hirundines, which are 49-73% lower than those of other passerines of the same size. Although swallows are often considered to fly fast, they usually clock in at no more than about 30-40 km per hour during foraging, reaching up to about 50-65 km per hour when travelling between sites or on migration. In two genera, *Psalidoprocne* and *Stelgidopteryx*, the male's outer primary has a rough outer edge, caused by the barbs being recurved to form minute hooklets. The function of this serration is not known, but it may produce a sound used during a territorial or courtship display.

Also vital during aerial manoeuvres is the more or less forked tail, which the bird can spread wide, raise, lower or twist in order

*The enigmatic and highly specialized **African River Martin** is found along forested rivers and in coastal savanna in Central Africa, where it nests in large colonies on riverine sandbars, sand dunes and other littoral habitats. Outside the breeding season, birds roost in reedbeds and other forms of emergent wetland vegetation. The African River Martin is a member of the subfamily Pseudochelidoninae, which contains just two species that possibly represent relicts of a formerly more widespread group of birds. This subfamily differs from other hirundines by having a large syrinx and half (not complete) bronchial rings.*

[*Pseudochelidon eurystomina*, Gamba, Gabon. Photo: Michel Gunther/ Bios]

*Over most of its enormous range the **Barn Swallow** is so closely tied to rural and urban environments that it could be considered a commensal of man. In Europe and North America it is a rural species, closely associated with pastures and farmyards, especially those used by cattle, and in such situations nests are often placed in barns and other outbuildings. Elsewhere, in North Africa and Asia, the Barn Swallow has invaded our cities and towns, and nowadays few nests of this species are sited in natural locations, such as cliffs or tree cavities. Instead most nests are placed on man-made structures, such as buildings, bridges and culverts, and this trait must have contributed greatly to its success. However, recent declines have been noted across parts of its range. These are attributed to agricultural intensification and other changes in policy which have effectively removed cattle from the landscape and caused declines in the quality of farmland habitats.*

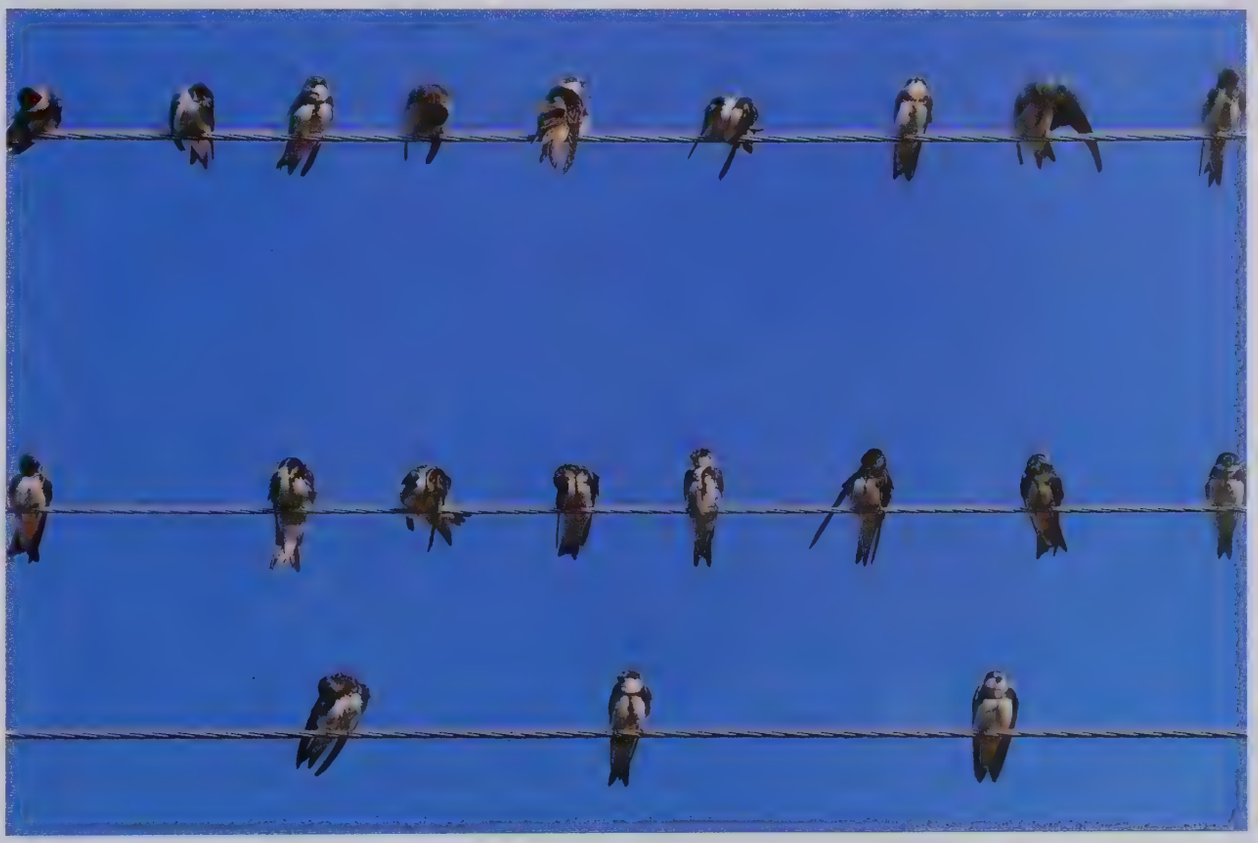
[*Hirundo rustica rustica*, Somerset, England. Photo: John Daniels/ Ardea]

to slow down or turn. The tail, particularly the leading edges formed by the outer rectrices, provides lift, and it also influences manoeuvrability, rate of climb and acceleration. Hirundinids differ in the fork depth of the tail and in the presence or absence of streamers. In part, this is related to the type of insect that they hunt. Species, such as the Barn Swallow, that chase large fast-flying insects and have to change direction frequently, have long outer tail feathers which provide more lift and enable the bird to turn tightly. Elongated outer rectrices, however, also play a part in the acquisition of a mate, for studies have demonstrated that long-tailed male Barn Swallows are more attractive to females than are short-tailed ones (see Breeding). Interestingly, hirundines possessing these tail-streamers are sexually dimorphic, with males having a longer tail than that of females, the outer rectrices sometimes so elongated and tapered that they appear wire-like. An extreme example is the Montane Blue Swallow, males of which have a spindly outer tail averaging 135 mm in length, compared with the female's 69-mm tail. Streamers are most characteristic of the genera *Atticora*, *Psalidoprocne*, *Cheramoeca*, *Pseudhirundo*, *Hirundo* and *Cecropis*.

The members of this family have weak legs and feet, adapted more for perching than for walking and running. Not only are the leg muscles smaller than those of other passerines but there are also fewer of them. When on the ground, hirundines are nevertheless mobile; they will adopt a shuffling walk and will occasionally run. Northern House Martins and other mud-nest builders often land on the ground in order to collect mud, and many species also do so to collect grass or other vegetation for the nest, to pick up grit as an aid to digestion or as a calcium supplement, to sun-bathe (see General Habits), to attempt a forced copulation, or occasionally to feed on accumulations of insects or other prey, such as amphipods (see Food and Feeding). In addition, species that excavate burrows or nest on cliffs tend to have strong claws.

The hirundinid bill is typically short and flat, but the gape is wide, the latter an adaptation for plucking insects from the air while in flight. The size of the bill varies with the type of insect taken, Barn Swallows, which feed on large prey, having a stouter bill than that of Northern House Martins, which eat small ones. During the nest-building process, the bill is also used as a means of carrying mud or digging a hole. Sand martins are specialist excavators and have a relatively small, conical bill, which makes the action of slashing at a substrate easier and more effective. Hirundines have strong jaw muscles, designed in part for snapping at insects and in part for manipulating mud or digging into sand. In addition, their loral feathers act as a lens shade, a further adaptation for catching flying insects.

Many hirundines have a contrasting plumage pattern of dark upperparts and lighter underparts. They are often glossy, metallic blue or green above and often white or rufous, and sometimes streaked, below. In at least three species, the Northern House Martin, the Barn Swallow and the Collared Sand Martin, the plumage exhibits strong ultraviolet reflectance. Other common markings include a pale or rufous forehead, throat and/or rump, a partial or full breastband, and white patches in the wings or the tail. The colour patterns probably have a number of functions. The facial pattern of juveniles of the colonial-nesting Cliff Swallow (*Petrochelidon pyrrhonota*) and Cave Swallow is highly variable and may help parents to recognize their offspring in the sometimes large crèches in which fledglings gather (see Breeding). As nest-owners often sit in the dark entrance to their nest, a pale throat or a pale forehead patch, like that of the Cliff Swallow, probably makes a conspicuous signal to intruders that the nest is



*Many hirundines are gregarious outside the breeding season, but within this context amongst these **Northern Rough-winged Swallows** it can be seen that a regular distance is observed between neighbours. The degree of tolerance hirundines show towards conspecifics varies but, as is to be expected, is greatest amongst the colonial species. During the breeding season most hirundines, including colonial species, fiercely defend their nests and the surrounding area from intruders, and a few even defend larger feeding territories. Despite this, many hirundines frequently come together outside the breeding season to form spectacular, and sometimes enormous, flocks that migrate, feed and roost together.*

[*Stelgidopteryx serripennis*, Belize. Photo: Terry Whittaker/ FLPA]

occupied. During courtship, male Barn Swallows, when they display to females, spread out the tail to show off the white spots in the feathers. Red and white patches may indicate an individual bird's health to potential mates. Carotenoid pigments give the Barn Swallow's throat patch its red coloration, but they are also necessary for the bird's immune system; it is possible, therefore, that only healthy males have enough carotenoid to spare to create a flashy signal that will attract females. Similarly, the white parts of feathers are more susceptible to being damaged by feather lice (Mallophaga), so that only parasite-free males may be able to afford to show off large areas of white in the tail.

Females are usually like males, if a bit duller, and, among species in which the male has an elongated tail, the female's tail is normally shorter. Juveniles are generally duller and browner than adults, often with pale fringes on some of the feathers and a short tail. Wing and tail lengths may increase with age, but in

*At certain times of the year, utility wires festooned with hirundines, such as these **Collared Sand Martins**, are a common feature in many temperate countries. Many species of migratory hirundines start to congregate in the latter part of the breeding season and stay in loose flocks during migration, later to attend large communal roosts at their winter quarters. At the end of the breeding season flocks gather, as roosts of non-breeding birds are joined first by males deposed from nests during the latter stages of brood-rearing and later by females and young. By grouping together, individuals benefit from increased protection from avian predators and the sharing of body heat during cold weather.*

[*Riparia riparia riparia*, Kurgaldzino Nature Reserve, Kazakhstan. Photo: Hanne & Jens Eriksen]

Constant aerial activity is a demanding business but one to which hirundines are well adapted. The energetic pursuit of prey during hot weather can lead to overheating, and one method of losing heat is the wing-raising behaviour illustrated by this ***Brown-chested Martin****. Wing-raising exposes a greater body surface area and greatly accelerates heat loss. Other methods include panting, gaping and dangling the legs in flight. Most hirundines will, however, simply avoid flying in very hot conditions and shun the skies during the middle of the day, preferring to rest up in the shade. It is during these non-feeding periods that birds indulge in comfort behaviour. Preening activity, as illustrated by this* ***Greater Striped Swallow****, is essential for maintaining the body feathers, which help to regulate body temperature, and the flight-feathers, which are so important to such an aerial group of birds. Hirundines also scratch their plumage and indulge in a variety of other feather-care activities common to a great many bird families. One rather less usual method that is commonly observed in the hirundines is the aerial bathing manouevre which involves flying low over stretches of open water and wetting the body by briefly hitting the surface, sending up a small cloud of spray.*

coloration yearling hirundines are mostly the same as older birds. There are, however, a few exceptions to these general principles. The most striking age and sex differences are seen in the *Progne* martins. Adult male Purple Martins are all dark blue, whereas adult females have a greyish collar and underparts, yearling males are like adult females but with some blue feathering below, and yearling females are paler and duller than adult females. In addition, first-year males are shorter-winged and shorter-tailed than adult males, whereas first-year and adult females are equal in size. There are also geographical differences, with western yearling males being even more like females than are those in the east of the range. The function of this variation is still unclear. Yearling male Purple Martins do not seem to gain any benefit from resembling females during the breeding season, such as a reduction in aggression from adult males or easier acquisition of a territory. They may, however, benefit in the non-breeding season, as both yearling males and adult females are dominant over adult males at roosts. First-year female Tree Swallows also differ in colour from older birds, having brownish upperparts with few greenish-blue feathers. Because of the severe competition for nest-sites, they often fail to acquire one of their own, and their brown coloration may, therefore, signal a subordinate status, reducing aggression from territorial pairs while they are searching for a place to breed.

Hirundines moult once annually, after breeding. Since they have to fly efficiently in order to hunt insects, they may take several months to complete the moult, Barn Swallows requiring 4·5-6·5 months. In addition, the duration of the moult depends on the weather; drought, for example, can both reduce insect abundance and increase the distance of roost-sites from feeding sites, concomitantly reducing the rate of moult. Hirundines breeding at high latitudes do not have sufficient time in which to complete the moult after breeding and before bad weather forces them to migrate, so the main part of the moult often occurs in the non-breeding quarters. However, they often start to moult some feathers, particularly those of the body, the inner primaries, the wing-coverts or an inner tail feather, before commencing migration, and Tree Swallows sometimes start even while still engaged in breeding. The extent of the moult before migration is variable, Collared Sand Martins replacing a few body feathers and inner primaries, while Tree Swallows complete half of their moult. The process can continue during migration, as is the case with, for instance, Tree and Northern Rough-winged Swallows. Some species, the Barn Swallow and the Purple Martin being examples, then suspend the moult while crossing areas where feeding is difficult or impossible, such as the Sahara Desert or the Gulf of Mexico. In contrast, eastern populations of Northern Rough-winged Swallows delay their crossing of the Gulf of Mexico, remaining on the northern Gulf coast for about two months, until they have finished moulting their flight-feathers. On the opposite side of the world, the Nepal House Martin (*Delichon nipalense*), resident in southern Asia, has an unusually protracted primary moult throughout the breeding season, and the moult is suspended from mid-November to mid-March, when the weather is very cold. Juvenile hirundines tend to start the moult, particularly that of the flight-feathers, later than do adults.

The body feathers and the wings are typically moulted first, followed by the tail feathers, but the outer primaries and rectrices may still be growing when the bird returns to its breeding area. The body moult is variable, starting with the back, breast and belly and then the crown, chin and rump in the case of Tree Swallows, but these areas of the plumage are replaced concurrently by Northern Rough-winged Swallows. The primaries are shed in sequence from the inner to the outer ones. The secondaries are replaced either from the outer feathers inwards towards the body or in two series; in Northern Rough-winged Swallows, for example, moult of the inner series S8-S9-S7 begins before the outer series S1-S6. The tail feathers are moulted from the centre outwards, but the outermost feathers may be replaced before the penultimate, or even the antepenultimate, ones. The wing and tail feathers are usually moulted symmetrically, so that the bird can still fly efficiently.

Habitat

Swallows and martins are found in a wide variety of mainly open or semi-open habitats, especially near water, ranging from savanna and farmland to coastal mangroves and forested rivers, and from remote mountain crags to bustling towns and cities. They also breed at a wide range of altitudes, from sea-level up to about 4000 m.

*Hirundines tend to be enthusiastic but rather unaccomplished songsters. Typically, **Tree Swallows** are highly vocal: not only do they have a territorial song, but up to fourteen separate calls have been identified. These calls transmit information that is essential for successful mate selection, copulation, nesting and brood-rearing. The two birds here may be indulging in courtship behaviour, when the male gives specific calls which entice the female to view a nest-site or to solicit copulation. Although hirundines are socially monogamous, extra-pair paternity is very common in Tree Swallows and so the exchange seen here might actually be an opportunistic encounter during an absence of both birds' true partners.*

[*Tachycineta bicolor*, Ohio, USA. Photo: Dave Maslowski/ Maslowski Productions]

To a certain extent the diet of many hirundines reflects the spatial and temporal availability of the flying insects that form the bulk of their prey. Although dietary composition is largely unknown for many species, that of the ***Violet-green Swallow*** *is relatively well studied, consisting mainly of leafhoppers, leafbugs, flies, ants, wasps, bees and beetles. This species often feeds much higher above the ground than its congeners, presumably an example of the kind of niche separation that helps to reduce direct competition between sympatric hirundines and other birds with similar feeding methods, such as swifts (Apodidae).*

Many species make their nests in a pre-existing cavity, such as an old woodpecker (Picidae) hole in a dead tree, an abandoned burrow in a riverbank, or a rock crevice, and are not "primary excavators". This is the case for the *Tachycineta* swallows and the *Progne* martins, for example. The natural breeding distribution of these species is therefore limited to such habitats as woodland, crags and sea cliffs where sites of this kind are available. They do, however, readily take to using artificial sites, including the roofs of houses, pipes, streetlamps and nestboxes; such sites have increased the type of habitat suitable for breeding in, such as open grassland, tundra, towns and cities lacking natural nest-sites. The eastern population of the Purple Martin, for example, now breeds almost entirely in human settlements, in specially provided "houses". Other species, as typified by the *Riparia* sand martins, excavate their own burrows and are also limited by the availability of suitable substrates such as riverbanks, but they, too, often utilize artificial sites, such as road cuttings, and sandy banks in quarries, thereby extending the range of habitats in which they can thrive. Because of erosion and changes in human usage, which both create and destroy breeding habitat, sites for burrows are often ephemeral, however, sometimes leading to changes in local abundance and distribution of tunnelling species.

Members of the *Hirundo* group (see Systematics) have taken another path. They build their own "cavity" of mud, which they can attach to a variety of natural substrates such as cliffs, trees, cave ledges and riverbanks. It is this group, however, that has exploited humans the most, using bridges, culverts, wells, barns, houses and other buildings as nest-sites. For some mud-nest builders, such as the White-throated Blue Swallow (*Hirundo nigrita*), this is a relatively new habit, but others, such as the widespread Barn Swallow, have been making their nests in our homes for centuries and now rarely use natural sites, breeding mainly in human settlements, including busy cities, or along roads and railways.

Mud-nest builders are most diverse in Africa, where seasonally dry habitats have been available during the course of their evolution. As mud nests can crumble in conditions of high humidity, humid tropical areas are less suitable for these species. In contrast, cavity-nesters are most diverse in the New World, perhaps because of a greater abundance of sites available in the forests and mountain chains of these continents.

Many hirundines are fairly catholic in their choice of breeding habitat. For these, the presence of a nest-site and a good food supply are the important factors, rather than whether the site is a coastal cliff, a barn on farmland, a bridge along a road, or a building in the centre of a city. These species are often widespread and common, the Barn Swallow, for example, breeding throughout most of North America, Europe and Asia. Other species are more likely to be found in particular habitats or at certain altitudes. Thus, in Africa, Lesser Striped Swallows (*Cecropis abyssinica*) generally occur in wooded areas at elevations of up to about 2000 m, whereas Greater Striped Swallows (*Cecropis cucullata*) in the same geographical range are more typical of open grassland at higher altitudes. Members of the tree swallow group are typically associated with waterbodies such as lakes and other wetlands, including mangroves. Many hirundines are, or were, typical of upland areas; while some, such as the White-tailed Swallow, are still found only at high elevations, others, such as the Eurasian Crag Martin (*Ptyonoprogne rupestris*), have extended their altitudinal range by nesting on buildings in lowland areas, as well as on rock faces. A few hirundines are specialists or are restricted in habitat type. One subspecies of the Purple Martin, for example, breeds mainly in holes in saguaro cacti (*Carnegiea gigantea*), and the Bahama Swallow typically uses holes in Caribbean pine trees (*Pinus caribaea*). Some, such as the Square-tailed Saw-wing (*Psalidoprocne nitens*) and the Forest Swallow, are typical of forest clearings, and several species, including the African River Martin, Brazza's Martin, the Congo Sand Martin (*Riparia congica*), and the White-banded (*Atticora fasciata*), Black-collared (*Atticora melanoleuca*) and White-throated Blue Swallows, breed on forested rivers.

Besides sites for breeding, hirundinids also need a good supply of their food, flying insects. Vegetation such as trees or scrub provide a source of insects, as do ponds, lakes and similar waterbodies. Water is important in the life-cycle of many insects and, as a consequence, provides a good source of prey for hirundines, especially in adverse weather when flying insects are

scarce elsewhere. During cold spells in spring, especially, large numbers of swallows of several species can concentrate at a few waterbodies that provide the only good feeding at the time. Hirundines, therefore, often feed around trees and over water. When breeding, they tend to forage close to the nest, often within a few hundred metres of it, so that good foraging habitat is an essential part of the breeding habitat. In addition, the method of foraging, that of catching insects in flight, requires sufficient open space in which the birds can manoeuvre, thus limiting their distribution in forested areas, apart from clearings, forest edge and waterways. As well as providing a good habitat for feeding, water is often a beneficial feature of the breeding site: nests built over water are better protected from predators than are those constructed over land.

For roosting, hirundinids either use nests and burrows (see General Habits) or exploit tall vegetation such as trees, reedbeds, marshes or such crops as maize (*Zea mays*). They also roost in cliffs, under bridges and, in towns, on building ledges, in trees or on wires. Northern House Martins, however, as well as using nests, are thought to sleep on the wing, in particular in their winter quarters in Africa, from where there are few documented records of roosting individuals.

Migration routes and wintering areas need to provide both good feeding and good roosting sites, but a wider variety of habitats, including wetlands, grassland, coasts and others, can be exploited than is possible during the breeding season. In their non-breeding quarters, hirundines are more mobile and are able to feed farther from their night-time base, and over more varied habitats, than they can when tied to a nest. Barn Swallows in southern Africa, for example, forage over grassland, woodland, forest edge and, especially, wetlands and tend to range up to about 100 km from the roost, whereas, when breeding, they favour farmland and usually feed within a few hundred metres of the nest.

General Habits

The majority of hirundines are not very social in the breeding season, when they nest solitarily or in loose groups, and forage alone or in pairs or small flocks. Some, such as the Mangrove Swallow, are highly territorial, feeding mainly in their own large territory, but many species defend only the nest and its immediate vicinity, with several pairs perhaps feeding over the same area. A few species are truly colonial, building nests close to each other and feeding in large flocks. Typical examples of these are Preuss's Swallow (*Petrochelidon preussi*) and the Cliff Swallow.

On the breeding grounds, pair-members generally roost at the nest once they have claimed a site and the nest itself is substantially built. Before that, they roost in sheltered sites, as on rafters in buildings or in trees or burrows. As breeding progresses, it is usually the female that remains on the nest at night, especially when she has eggs to incubate or young nestlings to brood (see Breeding); her mate may join her if there is room, or else perch close by. As the nestlings approach the fledging stage, their parents often perch outside the nest, and males, especially, may roost elsewhere, joining communal late-summer roosts. Non-breeding individuals, too, often roost communally.

Once a brood has fledged, the more solitary species stay in family groups for a few days or weeks. Among the more sociable ones, however, the juveniles form crèches (see Breeding). In the case of non-migratory species such as the Nepal House Martin, the partners, after breeding, may remain at the nest-site, roosting in the nest, but hirundines are generally gregarious at this time, feeding, perching, preening, migrating and roosting in flocks. The act of assembling in a group may provide protection from avian predators such as sparrowhawks (*Accipiter*) and hobbies (*Falco*). In a flock, because there are more individuals that may detect a predator, any one bird can afford to be less vigilant and is, moreover, less likely to be caught, as a predator may find it difficult to single out one individual from a large group. Late-summer daytime flocks may consist of just a few tens of birds but, later, larger groups form, especially at roosts, which can contain thousands or hundreds of thousands of individuals. Hirundines often assemble at the roost-site an hour or two before sunset and perform spectacular aerial manoeuvres, dense flocks flying to and fro over the site before dropping into the roost. Flocks and roosts often consist of more than one species of hirundine and sometimes include other bird species. Purple Martins, for example, often roost with Brown-chested, Grey-breasted and Southern Martins in their winter quarters.

Within a perching or roosting flock, the individual birds are not always very sociable. Barn Swallows maintain an average distance from each other of 12 cm, and more when preening. Those that approach too closely will gape at or peck each other. The more sociable Cliff Swallows will perch 10 cm, and sometimes only 3-4 cm, apart, but they will also try to knock other individuals off their perch or peck at them, forcing them to fly off. Purple Martins are less aggressive towards each other and will perch 5-6 cm apart, and Collared Sand Martins are content with distances of only 3-4 cm. Individuals entering a roost will also try to displace others from favourable central or upper positions.

Whilst diet in hirundines is largely dictated by prey availability, niche separation is achieved by the fact that different species single out prey in favoured size classes. Large Progne *martins, such as the* ***Southern Martin****, have a marked preference for larger prey items, for example dragonflies, whereas other hirundines specialize, for instance, in the capture of large flies or small, but numerous, swarming insects. Southern Martins will feed at different levels above the ground, depending on the circumstances. Birds can often be seen foraging alone, but they will also gather together in small groups.*

[*Progne elegans*, Patagonia, Argentina. Photo: Yves Bilat]

*Coughing up pellets is a daily task for busy insectivorous birds, such as the **White-winged Swallow**. Many insects are characterized by hard exoskeletons composed of chitin, parts of which are simply indigestible. After food items are ground up in the gizzard, any hard fragments are ejected via the mouth, in the form of compact pellets, rather than passing through the remainder of the digestive tract. The diet of this species includes flies, ants, wasps, beetles, butterflies and moths, which are taken during long, fast flights, often over extensive open stretches of water.*

Hirundines spend much of the day in feeding, especially when they have nestlings. Early in the breeding season, they typically spend many hours away from the nesting site, especially in the afternoon. Nest-building, on the other hand, is more of a morning activity, sometimes extending to the early afternoon, this period perhaps being selected in order to allow enough time for mud, where this is used, to dry before nightfall, and to allow the birds to acquire sufficient food to last the night. Nest-building also tends to be undertaken in bouts between periods of foraging. Once the female starts to lay, the partners stay closer to the nest and return more frequently. This trend continues during incubation until, when they have nestlings to feed, they are visiting the nest every few minutes (see Breeding). After breeding, hirundines spend more time in loafing on wires or in trees and in preening, and again leave the breeding site for long periods in order to forage. As hirundines are visual hunters, they feed during the day in full light. Furthermore, they require temperatures that are high enough for their insect prey to be active. At high latitudes, for example, the light at dawn may be adequate, but it may be too cold for insects to be flying, and the birds therefore pass this time in perching, preening or indulging in mating activities. High temperatures can also affect foraging, by making insects more active and difficult to catch. Foraging usually continues until near sunset, although the birds are able also to catch insects after dusk when artificial light sources are present.

Feeding on insects in flight means that hirundines are exposed to the prevailing weather for long periods. In hot weather, hirundines will gape, pant and raise their wings, and also extend their legs while in flight, in order to lose heat. In the tropics, especially, they often avoid foraging during the hottest part of the day, choosing instead to perch in shade, and feeding more in the cooler hours of the morning and late in the day. Purple Martins have been recorded as soaking their belly feathers before returning to brood nestlings, perhaps as a means of cooling the chicks. Strong wind and rain also affect the ability of hirundines to forage; whereas Purple Martins usually just sit out a spell of rain, Barn Swallows will seek out alternative feeding sites where insects are still active. In very cold weather, both when roosting at night and during the day, hirundines often huddle together, sometimes on top of one another, in a nest, burrow, nestbox, cavity or other sheltered site, which probably helps them to retain body heat. In various instances, more than 100 Collared Sand Martins were found clustered inside a dovecote, eight Barn Swallows inside a single nest and, similarly, 14 Northern House Martins in a single nest. Individuals in such groups are sometimes in an apparently torpid state. White-backed Swallows found in this condition, for example, have been cold to the touch and apparently lifeless, but have revived and flown away when warmed. It seems possible that this behaviour lent credence to the early theory regarding the whereabouts of Barn Swallows in the winter, namely that they hid in rock crevices or under water and remained torpid until the spring. The body temperature can drop in such conditions, which helps individuals to conserve energy, and this, together with clustering, may allow them to survive for a day or so without food in severe weather. In experiments, it was found that Northern House Martins, by clustering, reduced their metabolic rate by a quarter during the day and by a third at night, and in extreme conditions they became torpid, lowering their night-time body temperature from the normal 36-40°C to less than 30°C.

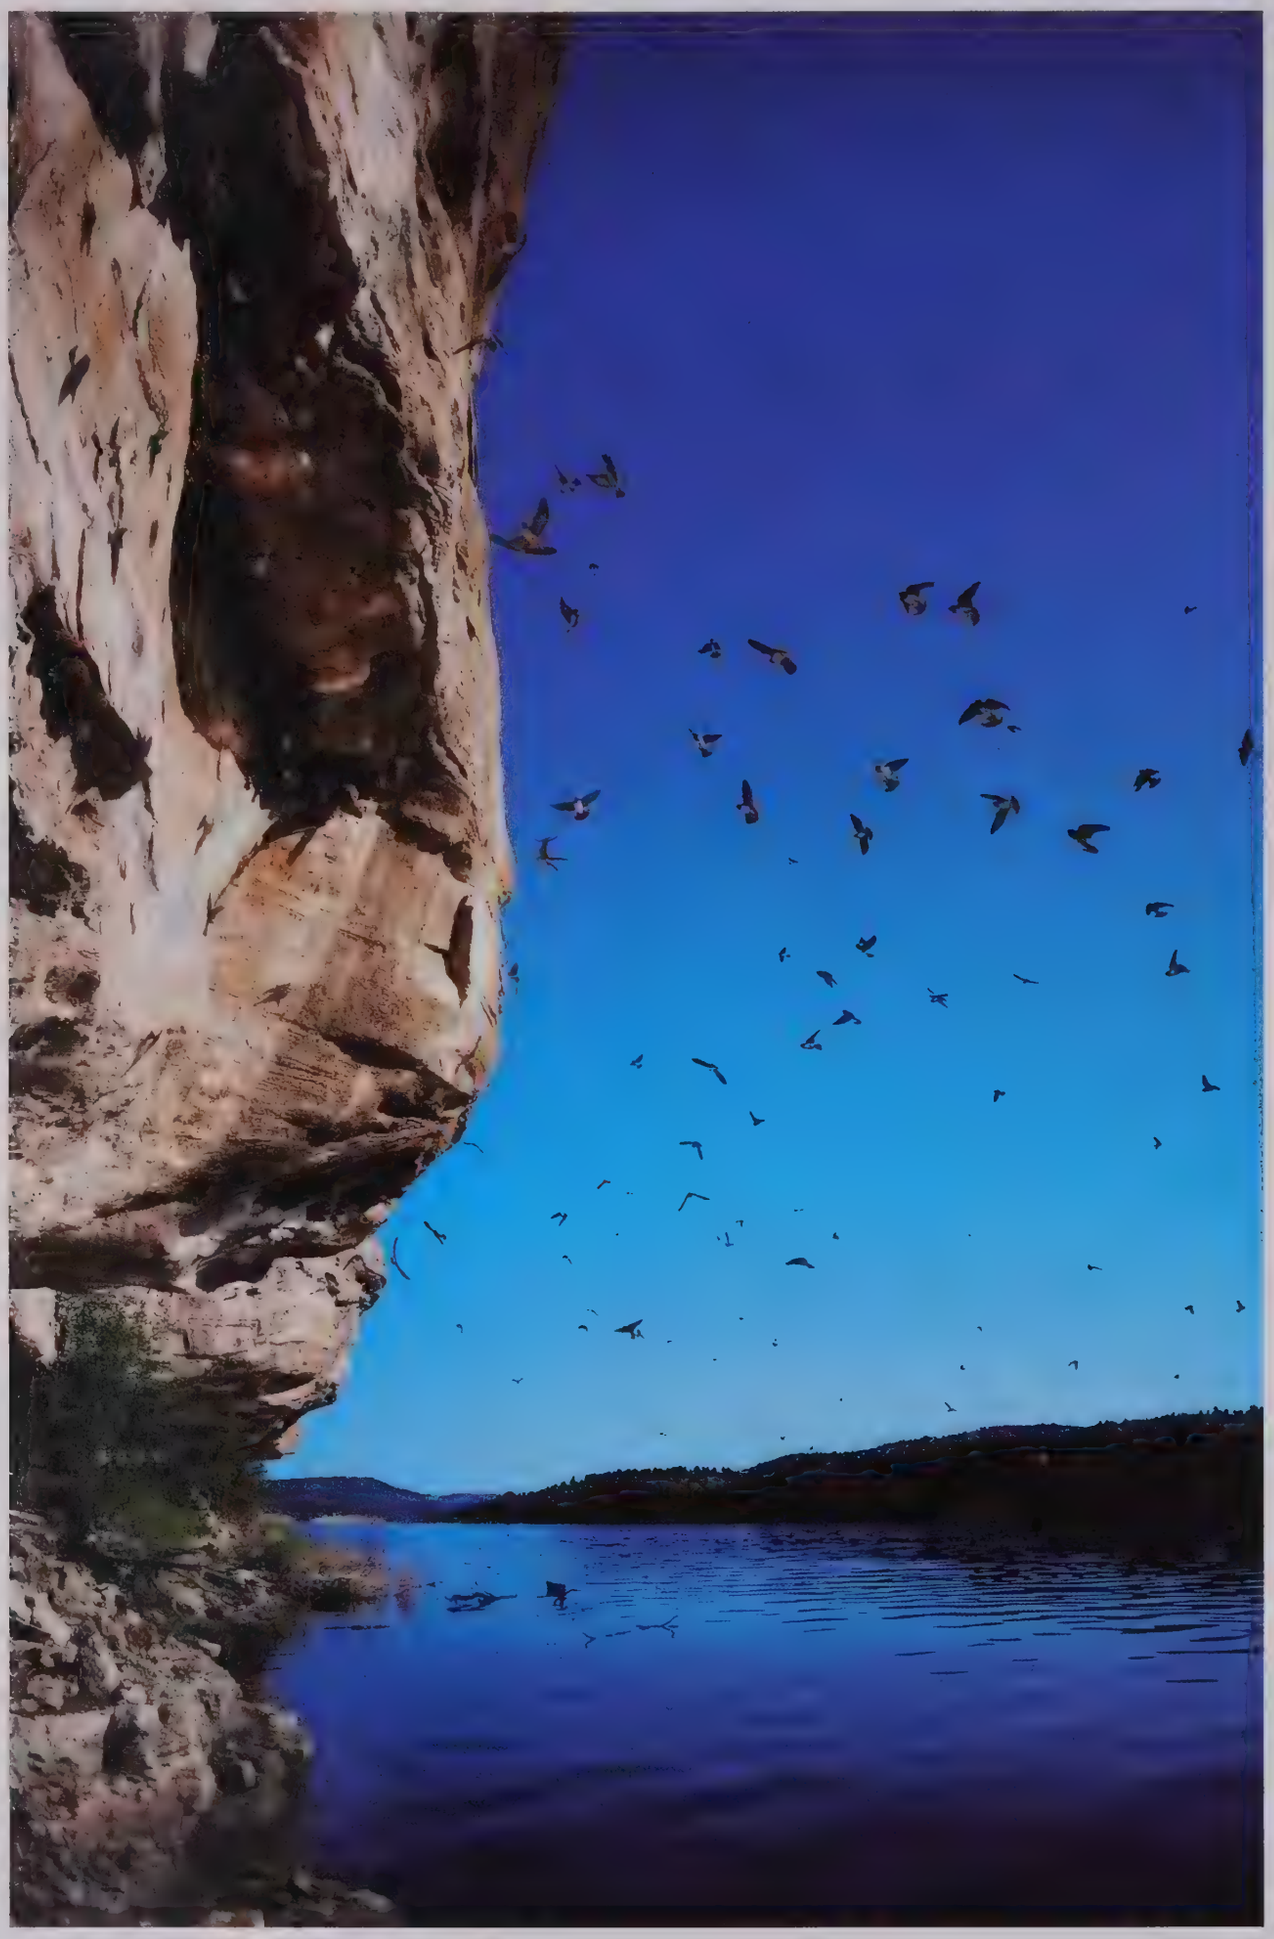
Because they fly for much of the day, hirundines need to keep their feathers in good shape and they regularly preen them. Preening is most frequent early in the morning and late in the evening, before and after the main feeding period. Hirundines also scratch, both while perched and in flight. When bathing, they usually skim over water and hit the surface briefly, sometimes more than once, so as to splash themselves, but they will also wade into shallow water. In addition, they are known to bathe in dew and to dust-bathe. Another regular activity among swallows and martins is that of sun-bathing. This takes place on a cliff face, on bare ground, on a wire or the roof of a building or nestbox, even on hot metallic surfaces, where the bird ruffles its feathers, fans the tail and stretches out the wings, sometimes lying on one side to expose the other to the sun, and also opening the bill and panting. These bouts of sunning can last for several minutes and are thought to help in controlling ectoparasites.

Among group-living species, preening, bathing and sun-bathing can be communal activities. One study demonstrated that Cliff Swallows, by assembling in large groups to preen, were able to spend more time in attending to the plumage and less in watching out for predators.

Voice

Swallows and martins do not have the most mellifluous of voices, the male's song often being no more than a series of twittering or

grating notes. Male Tree Swallows sing apparently as a means of proclaiming ownership of a territory. Male Barn Swallows, on the other hand, sing in order to attract females during courtship, and they may be showing off their good qualities: they give a twittering song more when they have few parasites and a healthy immune system, and females prefer males with complex songs. Barn Swallow songs also vary with the size of the breeding group and the individual male's testosterone level. Purple Martins and Tree Swallows have a distinctive dawn song, delivered before daylight while the bird flies high up over the nest-site, perhaps to attract conspecifics to the group.



While both male and female Collared Sand Martins sing, female hirundines often either do not sing or have their own song. Barn Swallow females, for example, twitter, and Purple Martin females have a "chortle" song which they utter during courtship. Juveniles emit a subsong, as also do males sometimes after breeding.

Apart from the song, the main vocalizations are the juvenile's begging call, an alarm call used when predators are seen, and a contact call used on many occasions between members of a pair or a family. The number of calls varies considerably among species, however, with colonial species tending to have fewer: Tree Swallows have 14, Purple Martins eleven, Barn Swallows ten, and Cliff Swallows only five. In the more vocal species, the vocalizations can include a contact call, used by parents when feeding or leading fledglings; a low-level alarm call and a high-level alarm call, the latter used when a predator is close to the

***Barn Swallows** and other hirundines frequently drink, and do so with typical panache by skimming low over the water and trawling the lower mandible through the water. Such low-level flight is typical of the Barn Swallow when foraging too, as it is at this height that its preferred prey of large flies are to be found. Favoured prey items during the breeding season include hoverflies, horseflies and blowflies, all of which demand the utmost speed and agility for their capture. The high energy output expended in capturing such mobile prey items is compensated for by the large size and calorific value of each insect. Other sympatric hirundines feed in higher strata and tend to pursue smaller, more numerous flying insects in a rather more relaxed and languorous fashion, thereby avoiding competition with the Barn Swallow. During periods of inclement weather, when flying insects are scarce, other hirundine species will also feed very close to the ground, but even then there is an element of separation, as Barn Swallows tend to feed over water more often than sympatric hirundines.*

[*Hirundo rustica rustica*, Sussex, England. Photo: Stephen Dalton/ NHPA]

*The breeding strategy of the **Cliff Swallow** relies heavily on the maxim that there is safety in numbers. Breeding colonies typically contain 200-400 nests, but one enormous colony contained a staggering 3700 nests. Nesting in this way, coupled with synchronous egg-laying, tends to swamp potential predators and avoids the high ectoparasite burdens, prevalent later in the season, that would certainly cause high mortality amongst very young nestlings. Hatching rates in this species have been shown to increase with colony size, which clearly demonstrates one of the benefits of colonial life. A range of other activities are also made safer or more efficient by group-living. Preening, for example, is a potentially hazardous occupation demanding a lot of attention and exposing birds to the risk of predation; it is accomplished more safely in groups. However, the biggest benefit of colonial living for this species comes in the level of co-operation demonstrated in locating and tracking food resources. Cliff Swallows feed on small, swarming insects that are mobile, local and ephemeral in occurrence, as well as often occurring significant distances from the colony. Individual colony members co-operate by giving a specific call to summon others when they locate a swarm. This behaviour allows individuals to return to feed young in the colony and then relocate the swarm again. In addition, birds that have been foraging with limited results can observe successful neighbours in the colony and simply follow them out to better feeding areas.*

[*Petrochelidon pyrrhonota*, McPhee Reservoir, Dolores, Colorado, USA. Photo: Claude Steelman/ Survival/Oxford Scientific Films]

Like other hirundines that build mud-nests and were formerly restricted to breeding on cliffs and rock outcrops, the ***Northern House Martin*** *has taken full advantage of the relatively recent arrival of a variety of man-made structures. Using sites such as this bridge for nesting on must have allowed this species to expand its range dramatically during historical time. This bridge arch admirably meets the requirements of a good nesting site. The nests are placed high up over water on an overhanging surface, features that are likely to restrict access by predators. In addition, approaching adults have a clear flightpath directly to the nest. It is also important, for species that build mud-nests, that the nests are well protected from the elements, because they are easily damaged by water or excessive heat.*

[*Delichon urbicum*, Spain. Photo: Bengt Lundberg/ Nature Picture Library]

nest; aggression and submission calls, uttered when individuals chase and fight each other near the nest and near their mates; enticement calls, used by males to attract a female to a nest-site and by both sexes to lead fledglings to a roost-site; and copulation calls, given prior to copulation. Some swallows apparently use alarm calls deceptively, when no predator is nearby, Barn Swallows in order to stop their mate from copulating with another male and Cliff Swallows to gain entry into evacuated nests. In addition, foraging Cliff Swallows have a specific call, the "Squeak" call, that signals the presence of a supply of insects and attracts other Cliff Swallows.

Soon after hatching, nestlings can be heard to make a faint, squeaky call, which develops into the juvenile call. This is used for soliciting food while the youngsters are still dependent on their parents; it then develops into an adult contact call. Adult Cliff Swallows can recognize their own offspring from these juvenile vocalizations, a necessity for this colonial species as fledglings from different nests mingle in large crèches (see Breeding). The Cliff Swallow nestling's call is individually distinctive by the time it is 15 days of age, several days before fledging, and the calls of nestmates are more similar to each other than are the calls of unrelated nestlings. Likewise, nestlings of the colonial Collared Sand Martin develop distinctive calls a few days before they fledge. In contrast, Barn Swallows appear not to recognize the calls of their offspring, which are much simpler than those of young Cliff Swallows; as Barn Swallows are more solitary, the parents can keep their brood separate from other families and therefore have less need to distinguish between fledglings. In the same way, parent Tree Swallows, another solitary species, also fail to recognize their offspring. Juveniles of both Barn Swallows and Tree Swallows, however, seem to recognize their parents' calls.

Other sounds made by hirundines include bill-snapping, especially during courtship. Cave Swallows have been recorded as making fluttering sounds with the wings, and a swishing sound as the wingtips brush against the wall of a cave. In addition, W. Lunk noted that Northern Rough-winged Swallows produce a shrill whirring sound; it is not known if this derives from the serrations on the primary feathers (see Morphological Aspects) and is part of a display.

Food and Feeding

Hirundines feed almost entirely on flying insects throughout the year. Unfortunately, the composition of the diet of many species is poorly known, and in some cases the only information is derived from the stomach contents of a small number of museum specimens. A few species, however, have been studied in some detail.

The insects taken by any one species generally come from a wide variety of taxonomic groups, and probably reflect the availability of the prey on the local level. In studies of Purple Martins and Cliff Swallows, for example, it was found that these species caught insects from 57 and 84 families, respectively. The types of insect taken include plant-bugs and true bugs (Hemiptera), such as cicadas (Cicadidae), along with beetles (Coleoptera), dipteran flies ranging in size from tiny midges such as chironomids to large hoverflies (Syrphidae) and horseflies (Tabanidae), dragonflies (Anisoptera) and damselflies (Zygoptera), caddis flies (Trichoptera), mayflies (Ephemeroptera), lacewings (Neuroptera), grasshoppers and crickets (Orthoptera), butterflies and moths (Lepidoptera), various hymenopterans, including parasitic wasps, bees, and ants, and termites (Isoptera). Different swallows and martins do, however, seem to prefer prey of certain sizes. Large martins of the genus *Progne* often take dragonflies and damselflies, Barn Swallows specialize on large flies, and Northern House Martins and Cliff Swallows concentrate on small, swarming insects.

Hirundines are very selective. They do not simply vacuum insects out of the air, but they choose which prey to pursue. Studies

*The **Collared Sand Martin** breeds in densely packed colonies, largely in response to the spatial distribution of suitable breeding sites, which tend to be scarce and often ephemeral. Suitable breeding sites consist of exposed, unvegetated earth and sandbanks into which the birds dig a tunnel terminating in the egg-chamber. Males start digging burrows on arrival at the colony, and when the work is half completed they start to sing and display to attract females. Courtship and copulation follow and burrow construction is completed by the pair. Although colonial, pairs are territorial and vigorously defend their burrows from intruders. Advantages of colonial life include enhanced detection of predators and, for older males, the chance of more frequent extra-pair copulation. Predators are undoubtedly attracted to the food resources represented by large colonies but few are capable of making significant impact on the glut of eggs and young present during the breeding season. In some species, hatching success is highest in the largest colonies, but high rates of fledging success appear to demonstrate a compromise, as it is usually higher in medium-sized colonies, perhaps reflecting the higher levels of competition for food and the higher ectoparasite burden that limit production in the largest colonies. Although in some parts of its range the Collared Sand Martin has undoubtedly been affected by excessive river engineering, which prevents the episodic natural creation of fresh breeding sites, it has not been slow to use the many new artificial sites brought about by human activities, such as sand and gravel extraction.*

[*Riparia riparia riparia*, Lake Kerkini, Greece. Photos: Manfred Pfefferle]

have shown that, in relation to the sizes of prey available in the environment, they take a greater proportion of larger insects on average. Nevertheless, even the bigger hirundines catch some small prey, especially when these form large swarms, such as those of flying termites or ants. Stinging insects are generally avoided, but some wasps and bees, especially stingless drones, are taken; further, hoverflies, which mimic wasps, are caught in large numbers. Hirundines eat a few non-insect prey, such as spiders drifting on threads in the air, or tiny amphipod crustaceans swarming on a beach.

A few hirundines also consume some plant food. Greater and Lesser Striped Swallows have been recorded as eating fruit, and Barn Swallows in their winter quarters feed on the seeds of acacia trees (*Acacia*), as well as on insects. Similarly, Tree Swallows include some seeds and berries, mainly of *Myrica* species, in their diet, particularly in the autumn, winter and early spring and in adverse weather, when insects are scarce. The last species is unusual in being able to digest the waxy coating of *Myrica* berries, and it is capable of surviving for long periods on a diet of berries alone; as a consequence, it can spend the winter months along the east coast of North America, occasionally as far north as Massachusetts, where flying insects are scarce, and it also returns to the breeding grounds earlier in spring than do other migratory hirundines.

The type of insect taken varies locally with the time of year and also with the weather conditions, both between years and over the course of a season, and even within the course of a day. In the cool early hours of the morning at high latitudes, for example, large flies may not be active but bees may be found at that time. Barn Swallows catch large flies mainly in the late morning and early afternoon, whereas plant-bugs are taken both earlier and later in the day. Dietary differences from one year to another can be substantial, as was demonstrated at a site in Scotland, where hoverflies formed 23% of that species' diet in a hot, dry summer, but only 9% in a cool, wet one. In addition, there are variations in diet between the non-breeding and breeding ranges if the bird migrates. Barn Swallows concentrate on flying ants more in the winter than they do in the summer, as these are abundant in their African winter quarters; termites, which are not available at the breeding sites, are also taken in the southerly, non-breeding areas, and these can be a particularly important source of food.

Nestlings, too, experience seasonal changes in the diet. In a study of Purple Martins, flies and aphids were fed to the nestlings mainly early in the season, and butterflies, true bugs and hymenopterans later on. Adult and nestling diets also usually differ somewhat, the parents eating smaller insects than those which they take back to the nest for the brood.

When feeding nestlings (see Breeding), hirundines usually catch several insects on a foraging trip and compress them into a food ball, or bolus, although large insects, such as some moths and butterflies, dragonflies and grasshoppers, are brought separately to the nest. A bolus can contain dozens of large insects or hundreds of small ones, varying considerably even within a species. In various studies of Barn Swallows, the average number of prey items per bolus ranged from 3·5 to 19, with total numbers of insects ranging from one to over 175. Species feeding on smaller insects collect more of them per foraging trip. In Scotland, for instance, food boluses of Barn Swallows contained 18 insects, on average, and those of Collared Sand Martins 60, and in the USA, at a site where Barn Swallows collected an average of only 3·5 insects per trip, Cliff Swallows were catching 18·7.

Otherwise, an intriguing report from southern South Africa was of a pair of Greater Striped Swallows that fed its nestlings not only with insects, but also at times with the seeds of *Acacia cyclops*. The parents, it seems, delivered these seeds, with the nutritious funicles still attached, more frequently in cloudy or adverse weather than they did on sunny days.

Different species of hirundine feeding in the same area avoid competing with each other, and with other aerial insectivores, by foraging at different heights or in different places, as well as on different sizes of insects. In Europe and Asia, Barn Swallows typically feed low over the ground, whereas Collared Sand Martins

Violet-green Swallows *have broken away from the ancestral burrow-digging habits of the early hirundines and nest inside pre-existing cavities. Nests are often situated in natural tree cavities and abandoned woodpecker holes. Because of these nesting requirements the Violet-green Swallow tends to occur mainly in wooded habitats, but it is also occasionally found in deserts and other open areas where suitable natural or artificial nest-sites occur allowing it to breed. Although this species readily uses nestboxes, interspecific competition for nest-sites can be intense, and elsewhere unsympathetic forestry management practices may be detrimental, for instance the removal of dead and diseased trees that are likely to contain suitable cavities.*

[*Tachycineta thalassina thalassina*, Colorado, USA. Photo: Dave Maslowski/ Maslowski Productions]

Bank-nesting species are not always colonial. The ***Northern Rough-winged Swallow*** *breeds in solitary pairs or small groups at sites including sand or gravel banks, quarries and road cuttings. Although this species will dig its own burrow if necessary, it prefers to adapt a pre-existing one. The bill is used to hack earth away and the resultant debris is cleared from the tunnel using the wings and feet. This species and other burrow-nesting hirundines share a common feature in possessing much stronger claws, an adaptation to facilitate digging. Burrows tend to be dug 30-100 cm into the bank, at the end of which an enlarged nest-chamber is constructed.*

feed at mid-levels and Northern House Martins at middle to high levels, but in all cases lower than Common Swifts (*Apus apus*), which are potential feeding competitors. In bad weather, however, flying insects, especially those normally found at high altitudes, are scarce, and any that are available are present mainly at low levels, particularly over water. In these conditions, all the species feed low down but they still segregate to some extent, with Barn Swallows foraging over water more than do the other species. The differences in foraging height and habitat are related to the type and size of prey taken; Barn Swallows hunt the largest prey, found near the ground, and Northern House Martins take much smaller swarming prey, found higher up. Thus, in one study, aphids formed only 0·3% of the diet of Barn Swallows, but 12·4% of the Collared Sand Martin's diet, 17·8% of the Northern House Martin's and 27% of the Common Swift's; nematoceran flies such as midges were also a small part of the diet of Barn Swallows and Common Swifts, constituting 12·6% and 9·8% respectively, compared with 22·2% for the Collared Sand Martin and 25·4% for the Northern House Martin. The Barn Swallow preferred brachyceran and cyclorraphan flies, such as horseflies and hoverflies, more than did the other three species; these two dipteran suborders accounted for 69·9% of its food intake, whereas the figure for the Collared Sand Martin was 47·1%, for the Northern House Martin 39·5% and for the Common Swift 37·1%.

Different species also have different styles of flight, depending on what they are hunting, and where. When chasing fast-flying, manoeuvrable insects close to the ground, hirundines fly swiftly, with frequent banking and turning, whereas gliding and fluttering flight are used at higher levels when hunting less agile, often aggregated prey. Barn Swallows typically fly actively, whereas Purple Martins are usually observed as they sail in circles, alternately flapping and gliding. Eurasian Crag Martins often fly back and forth along a cliff face, taking advantage of thermals.

Although the primary foraging method is that of hunting insects on the wing, hirundines sometimes perch to pick prey from the ground or other surfaces. This behaviour is most frequent either in adverse weather, when few insects are flying, or at times when crawling prey are particularly abundant, as during a termite emergence. South African Swallows (*Petrochelidon spilodera*) are particularly prone to feeding from the ground. Hovering and fluttering against vegetation to flush out insects, including caterpillars, is another technique sometimes recorded. Hirundines also take insects from water surfaces while in flight or pick up prey while hovering, and in the Neotropics the little White-thighed Swallow will glean prey items from leaves during rain. Swallows and martins are opportunistic and are quick to take advantage of good sources of prey, such as those presented by grass fires, by the actions of other animals, including people, in flushing insects from vegetation, by tractors ploughing fields, and by lamps that attract moths and other insects in the evening. In Western Australia, a Welcome Swallow has even been seen to feed inside a building, where it consumed flies gathered at a window.

During the breeding season, many hirundine species feed solitarily or in pairs. The male may accompany his mate during the egg-laying period, in order to keep other males away (see Breeding), but later in the season the pair-members tend to feed independently, taking turns to bring food to the nestlings or fledglings. In some species and subspecies, the partners also incubate in alternate bouts, and thus have to forage alternately during this stage of the breeding cycle. Feeding areas are not usually defended, however, and birds from several nests may feed over the same site at the same time. When insects are abundant or localized at a particular site, as with a swarm of ants, a mass emergence of mayflies or a mating swarm of flies, or in the lee of a hedge in strong winds, or when borne aloft in a thermal, large numbers of hirundines often converge and feed together, but the individual birds do not always benefit from being together with so many others.

Cliff Swallows, however, do gain an advantage from feeding in flocks, and those breeding in large colonies thereby increase their foraging efficiency and the amount of food that they bring back for their brood. Not only are they attracted to sites where they see that other birds are feeding but, in addition, in poor foraging conditions, they also utter special calls that draw in more birds to the source of insects. By attracting more foragers, they make it easier for themselves to keep track of the insects' location, even if the swarm moves; an individual can return to the colony and still find the swarm again, because it can see the birds still feeding there. Furthermore, a Cliff Swallow colony acts as an information centre: birds that have been unsuccessful in foraging watch out for any of their neighbours that have found food, and then follow them when they next leave to feed. At very large colonies, however, with thousands of nests, individuals can simply join the stream of foragers departing for the feeding site and

*The **Grey-rumped Swallow** breeds in burrows dug directly into the ground. Single pairs or small groups nest in this way in open habitats throughout a large part of sub-Saharan Africa. Open areas with short vegetation are favoured, such as riverine sandbars, grassy riverbanks and sand dunes, but the birds are also quick to use a range of suitable, appropriately managed artificial habitats, including airfields, cultivated areas and sports and recreation fields. In an absence of ground predators, other burrow-nesting hirundines may also nest in this way but how the Grey-rumped Swallow manages to breed successfully in burrows that are so accessible, and also prone to flooding, is a mystery.*

[*Pseudhirundo griseopyga griseopyga*, Marondera, Zimbabwe. Photo: Peter J. Ginn]

do not need to keep an eye on the neighbours. Group-foraging is important for Cliff Swallows because of the ephemeral nature of the prey on which they feed; the insects may be abundant, but the birds cannot predict where they will be. Barn Swallows, in contrast, have a more predictable food supply; scientists have looked for evidence that their breeding groups act as information centres, but have failed to find any, and it seems that, at most, the birds may simply be attracted to areas where other individuals are feeding. Whether the transmission of foraging information plays an important role in colonies of other hirundines is not clear. A study of a large colony of Collared Sand Martins, which feed on prey intermediate in size between those taken by Barn and Cliff Swallows, found some evidence of synchronous foraging, but other studies, of small colonies, did not.

When breeding, hirundines typically feed close to the nest, but some go farther than others, the species preying on small, clumped and ephemeral insects travelling the greatest distances. Thus, Barn Swallows feed within a few hundred metres of the nest and Collared Sand Martins up to 800 m from it, whereas Cliff Swallows fly up to 1·5 km and, occasionally, 6 km from the colony and Northern House Martins also travel several kilometres.

Foraging is greatly affected by the weather, which determines where insects will be available and of which sort they will be. In adverse weather, insects may be found at only a few sites, usually waterbodies. When it is cold, Purple Martins, which normally forage in open areas, will also seek food in towns, by hawking insects around cars. In particularly cold and/or wet conditions, especially in heavy rain, hirundines may be unable to feed at all. There is, however, a striking exception to this general rule. The Montane Blue Swallow, which lives at high altitudes in southern Africa, is well adapted for feeding in poor conditions, even in thick mist, as its body feathers are more effective in repelling water droplets than are those of most other birds.

In addition to food, hirundines ingest small bits of gravel and other items, such as mollusc shells, pieces of fish bone and eggshell. These "non-food materials" perhaps help the birds to digest hard-coated insects and also provide a calcium supplement, especially for females during egg-laying. Interestingly, the adults also feed their nestlings with such items.

Hirundines drink regularly. They do this by flying low over the surface of a waterbody, such as a lake, a small pond or a river, and dipping in the lower mandible to take up the water.

Breeding

As with feeding habits, knowledge of the breeding biology of many species of hirundine is scanty. On the other hand, a few members of the family, especially the Barn and Cliff Swallows, the Tree Swallow and the Purple Martin, have become model species for scientific study over the last few decades and are among the world's best-known birds. A great deal of research into sexual selection and coloniality, in particular, has involved these species. Extensive research has been carried out by A. P. Møller, on the Barn Swallow in Europe, and by C. R. and M. B. Brown and colleagues, on the Cliff Swallow in North America, and the findings are summarized in these authors' recent books, published in 1994 and 1996, respectively.

Wherever they breed, hirundines are dependent on a good supply of insect prey and, hence, on the duration of suitable weather conditions. In temperate regions, they breed in the late spring and summer, taking advantage of the burgeoning insect population at that time. The breeding season is, however, shorter at high latitudes. Barn Swallows, for example, start laying in March in Spain, but not until June in Finland. In subtropical and tropical regions, nesting can be limited to the wet season, when insects are most abundant, or can occur almost throughout the year, sometimes with peaks during the rains. The Wire-tailed Swallow, for instance, breeds mainly in the rains, but in some parts of its range, such as East Africa, it breeds in all months, with peaks of activity in some. In contrast, the White-throated Blue Swallow breeds during the dry season, so as to avoid the problem of its riverside nest-sites being flooded when the rivers swell during the rains. The need to collect mud with which to build a nest may also limit the breeding of some species during long dry periods.

Migratory hirundines generally return to their breeding grounds when temperatures there are rising and insects are becoming more plentiful. For species that migrate or disperse after breeding, an early return to the breeding grounds is advantageous. In some cases, as with Barn Swallows at high latitudes, pairs start to nest soon after arrival; the earlier they arrive, the more likely they are to have time for rearing two or more broods, whereas late-arriving birds may rear only one. In contrast, the single-brooded Tree Swallow arrives early in northern North America to claim a territory, but the arrival and breeding dates

Mud-nest building is a recent evolutionary trait in the hirundine family. This is reflected in the similarity in construction techniques and the narrow genetic distances between mud-nest building species. Indeed, the members of this group are so closely related that some species frequently hybridize. Mud-nest structures do, however, differ in their complexity and fall into three main categories, the more elaborate nests tending to be built by the truly colonial species. The most basic nest type is the simple, open mud cup, built for example by the Hirundo *swallows. Next comes the intermediate nest type built by the* Delichon *martins, consisting of an enclosed cup with a small horizontal entrance slit. The final nest type, built by species such as the* ***Streak-throated Swallow*** *and the* ***Cliff Swallow****, is the most sophisticated and aesthetically pleasing, and consists of an enclosed nest with an entrance tunnel. This last design presumably provides security in densely packed colonies because it is easily defended against intruding conspecifics. In both the illustrated species, pairs share the task of nest-building, and construction in Cliff Swallows takes up to 27 days, the job being quickest where party walls are shared with neighbouring nests. Both these species evolved to breed on cliffs and rock outcrops but have taken full advantage of artificial structures especially barrages, bridges and culverts, which allow them to build nests hanging over water.*

During the early part of the breeding season it is commonplace to come across hirundines, like this ***Mosque Swallow****, collecting mud at puddles and along the margins of waterbodies. When collecting mud, the bill is used to dig and transport it back to the nest-site. The mud-nest of this species is typical of the genus* Cecropis*, being fully enclosed and having a long entrance tunnel; the nest-chamber is lined with soft material, such as grass and feathers. Hirundines that build mud-nests require reliable sources of building material during the construction phase, and dry periods or droughts can delay or prevent breeding if the nests cannot be built.*

[*Cecropis senegalensis monteiri*, Zimbabwe. Photo: Mike Lane/NHPA]

are not linked. Early Purple Martins gain the advantage of being able to acquire the highest nest-sites, which suffer less predation from climbing predators than do low ones. In the case of Cliff Swallows, which also have only one brood in a season, the earliest birds may do little but forage for several weeks, whereas later arrivals begin nest-building within a few days. Hirundines are, however, vulnerable to bad weather, especially early in the breeding season, as this reduces their food supply. There have been many instances of large numbers dying during a prolonged spell of cold and/or wet weather, and local populations can be reduced or wiped out. In the Great Plains, USA, for example, thousands of Cliff Swallows died after six days of cold weather in 1996 and hundreds perished in a four-day period in 1992. Less severe spells of adverse weather early in spring, however, may occur every few years and limit the start of the breeding season. Brown and Brown found that such weather may select for birds that arrive later on the breeding grounds.

The number of pairs nesting together varies greatly, from one in the case of solitary species, such as the Mangrove Swallow, to hundreds or thousands in the most colonial species, such as the Cliff Swallow. Other hirundines will nest in groups if potential nest-sites are clumped, as happens particularly with artificial sites. Several pairs of Purple Martins, for example, will occupy a single multi-room "martin house". With these and other hole-users, natural groups may develop in certain sites, typified by large, dead trees where woodpeckers have excavated a number of holes, or cliffs with an abundance of natural crevices. Such birds do not necessarily benefit from living together, but, rather, they may breed in groups only because of a lack of alternative good-quality sites; the more sites there are available in an area, the more pairs can settle in it. Some individuals, however, may benefit from living in a group: older males, for example, may have more opportunities to copulate with females other than their mate. Younger males, on the other hand, may lose out by being cuckolded.

In general, there are few advantages to group-living. Indeed, there are disadvantages, one example being the fact that large groups of breeding birds can attract predators. Predators are detected more quickly in large Collared Sand Martin colonies than in small ones, but they also concentrate their attacks on the former. Large groups also result in more competition for resources and harbour more parasites. The most colonial hirundine species suffer the most from parasites, in terms of a reduction in fledging success. Although nestlings of these species, in order to counter the parasites, have a stronger immune response than do those of more solitary species, this is at the expense of a longer nestling period. Cliff Swallows, however, do benefit from being colonial, improving their foraging efficiency as a result (see Food and Feeding); they also detect predators more quickly in large colonies and, in big flocks with many birds watching for predators, each individual can afford to be less vigilant (see General Habits). Nevertheless, some individuals do best in small colonies, and others in larger ones. With Cliff Swallows, the preference for a particular colony size is inherited, individuals choosing to nest in colonies of a similar size to that of their parents. Some birds may be better suited to small colonies and others to large ones, depending, for example, on how well they can cope with the large numbers of ectoparasites in the bigger groups. Breeding success, too, can vary with colony size. In the case of Cliff Swallows, hatching success increases with increasing colony size, while fledging success and the survival rate of fledglings to their first year are highest in colonies of intermediate size.

Male hirundines generally return to the breeding grounds before the females, and older birds also tend to arrive before first-years. In north Texas, for example, adult male Purple Martins arrive some two months before yearling males and females. The males generally claim a nest-site, and start to advertise it or themselves to potential mates. Purple Martins do this by a conspicuous "Claiming-Reclaiming" display, in which the male flies up, circles over the nest-site and dives back down, and then enters the nest-hole and sings from the entrance. Male Collared Sand Martins similarly sing and fly in small circles around the entrance of the burrow, which they start to dig by themselves. Tree Swallows have a "vertical posture" display, in which the male points the bill upwards, droops the wings, sometimes also flicking them, and spreads and raises the tail. If a female shows interest, males may display conspicuous features of their plumage, such as the white throat on Collared Sand Martins and the long white-spotted tail on Barn Swallows, and draw the female's attention to the nest-site by flying to and hovering in front of it, giving a particular nest-advertising call, and entering the hole or perching and pecking towards it. The female is then likely to enter it herself and investigate the suitability of the site. Among

*Colonially breeding **Cliff Swallows** gather in noisy flocks to collect mud at suitable locations. Extra-pair copulation is common in hirundines and, when exposed during the act of mud-collecting, female Cliff Swallows often flutter their wings to deter opportunistic males from attempting copulation. Males of some species jealously guard their mates during the period when they are fertile to thwart other males, but others such as the Cliff Swallow have a more relaxed attitude, so extra-pair paternity is probably common.*

[*Petrochelidon pyrrhonota pyrrhonota*, Denali National Park, Alaska, USA. Photo: Rob Curtis/ The Early Birder]

other species, such as the Cliff Swallow, courtship is almost lacking, apart from some singing, and the male and female do little more than come to tolerate each other at a nest-site.

Pairs generally form on the breeding grounds. Individuals that have bred together in the previous year may come back to the same nest and breed together again. Females are choosy, however, sometimes sampling several males and nest-sites before staying with one male. In the case of Barn Swallows, they base their choice mainly on the length and symmetry of the male's tail, which may indicate his health and vigour. Studies in Europe have shown that males possessing a long, symmetrical tail have a good immune system, are resistant to parasites, and have good prospects of survival; they also pass on their good health and viability to their offspring. Females selecting these males are likely, therefore, to have healthy, long-lived offspring. Males with the most "attractive" tail acquire a mate soon after arrival on the breeding grounds and, further, the mate that they acquire is a good-quality one; moreover, they are also successful in obtaining extra-pair copulations and in avoiding being cuckolded themselves. These males, however, provide less help with nest-building and brood-feeding than do short-tailed males. Females mated to attractive males invest relatively more in reproduction, by laying more eggs, having more broods, and providing more food for the nestlings.

Cliff Swallows and Northern House Martins copulate inside the nest-cavity, while Barn Swallows often copulate on a perch close by the nest. Copulation is sometimes preceded by a short invitation display. The male Barn Swallow hovers above the female with his tail spread wide, whereas the male Cliff Swallow merely moves to the back of the nest and calls softly. Females are active in accepting or rejecting copulation advances. If they accept the advance, they often adopt a crouched posture, spreading the wings, raising the tail and keeping the body horizontal. The male may peck at and hold the female's head feathers in his bill while he mounts. Preening often follows copulation.

Pairs are typically aggressive in defending the nest-site. Owners often sit at the entrance to a nest, advertising their presence. They sometimes engage in threat displays, which can involve ruffling of the head feathers and vibrating of the wings, and also calling, as well as lunging at intruders or even chasing and fighting them. Fights, especially those between rival males, can be violent, with the combatants beating each other with their wings, pecking and holding each other with the bill, pulling out feathers, and grappling with the feet, even falling to the ground. Such fights sometimes result in injury or death. Individuals that fall into water during the course of conflicts can also drown.

The size of the area around the nest that is defended varies from one species to another and also among populations of the same species. Purple Martins in the eastern part of the range, where they nest in bird houses, usually have a territory based on several compartments within a single house, whereas those in natural nesting sites in Arizona have larger territories, with an average radius of 20-30 m, and occupied nest-sites are at least 100 m apart. Mangrove Swallows defend even larger territories, with inter-nest distances of 300 m. Species that nest in holes, or in nestboxes and bird houses, sometimes claim ownership of more than one potential nest-site. Purple Martins utilizing bird houses in Texas hold territories that encompass, on average, three nesting compartments. The spare sites may be used for roosting, or serve as an insurance against the first site being destroyed or taken over by other birds. Males and females can, however, have different reasons for defending more than one nest-site: male Tree Swallows are sometimes polygynous and may try to attract more than one female, whereas females may try to prevent other females from settling near their nest-site. For the colonial Collared Sand Martin, in contrast, the defended area is just the 8-12 cm around the burrow entrance, and for the Cliff Swallow it is no more than the interior of the nest once this has been built.

Hirundines are nearly always socially monogamous, one male nesting with one female. Rarely, a male will acquire two mates, but he will then generally give help almost exclusively to one of them; such polygyny seems to be most frequent among Tree Swallows. On the other hand, matings outside the pair-bond are common, at least among the better-known species, and probably throughout the family. Studies in Canada and Europe found that 22% and about 30%, respectively, of Barn Swallow nestlings had been fathered by a male other than the one feeding them. In the case of Purple Martins, it is the young males that tend to get cuckolded: in one study, up to 43% of chicks in the nests of yearling males were not the latter's offspring, compared with only 4% for adults. Females may benefit from copulating with other males by acquiring a genetically superior father for some of their offspring, and they may readily accept or seek out good-quality

extra-pair males. Older males are probably particularly attractive partners, as they have proven viability. Female Barn Swallows in Europe are more likely to seek out extra-pair matings if their own partner is a poor-quality, short-tailed male than if he is one with a long tail. Females may also find extra-pair mates that are genetically more compatible, or their behaviour is perhaps designed to increase the genetic diversity of their offspring. This is possibly the case with the Tree Swallow, which has one of the highest levels of extra-pair paternity known in the avian world. In various studies, 38-69% of nestlings of this species, in 50-87% of broods, were not sired by the male feeding them, and often several fathers had been involved in siring a brood. In contrast, one of the Tree Swallow's close relatives, the Mangrove Swallow, has a much lower incidence of extra-pair young, at 15%. This difference between these two *Tachycineta* species is thought to be due to the latter's lack of breeding synchrony, which means that there may be no fertile females available when a male is looking for extra-pair partners.

Males of several species often try to enter nests to copulate with the resident female. In one study of Northern House Martins, intruders appeared, on average, every ten minutes during the morning when the female was fertile. These males often have mates that have already laid a clutch, and they have therefore finished their own mate-guarding activities (see below). Opportunistic attempts at extra-pair copulation are also made away from the nest, as, for example, among Cliff Swallows at mud-collection sites. Mud-gathering females flutter their wings in order to prevent males from landing on them and copulating. Male Collared Sand Martins chase females at the colony, preferentially pursuing the heaviest females, which are the ones most likely to be fertile.

Male hirundines that gain paternity by cuckolding other males are generally already paired, and are often neighbours of the females with which they mate. Often present also at the breeding site are so-called "floaters", which are young, unpaired individuals looking for mating opportunities. The status of being a floater is sometimes only temporary. Purple Martin males with spare sites in their territory may eventually give one up to a persistent intruder, and older birds can even benefit from having young male neighbours, as they can cuckold them. In one study of Purple Martins, 13% of first-year males failed to obtain a mate, in contrast to only 4% of adult males and less than 1% of females. Unmated individuals may also hang around the nests of mated pairs while looking for an opportunity to replace or take over a partner. At Barn Swallow sites, these extra birds occasionally participate in mobbing predators, nest-building, incubation and brooding. In the case of Tree Swallows, unpaired floater males seem to do well out of this strategy, in one study fathering 13% of extra-pair nestlings. Because of the often intense competition for nest-sites among individuals of this species, there are often floater females, which sometimes become the second mates of polygynous males.

Competition for the chance to breed sometimes results in infanticide. With Tree and Barn Swallows, for example, a new male partnering a widowed female with young nestlings will kill the chicks so that the female will then mate with him. In addition, the killing of her brood may make a mother desert her present partner and mate with the killer. Moreover, female Tree Swallows looking for an opportunity to breed also commit infanticide.

As well as defending the nest-site, the male may actively keep intruders away from his mate, and his mate away from other males, during the egg-laying period in order to ensure that he is the father of her offspring. The extent to which males do this varies both within and among species. Some Purple Martins remain with their partner on trips away from the nest, whereas others rarely or never do so; first-year males that are good at such mate-guarding can thereby reduce the risk of being cuckolded. Males of the Barn Swallow and Violet-green Swallow stay close to their mate both at the nest and away from it, following her while she is feeding or collecting nest material, whereas Cliff and Tree Swallow males do not, concentrating instead on protecting the nest from trespassers or usurpers. In the latter case, the male may guard against being cuckolded by copulating more frequently with his partner: Tree Swallow pairs copulate, on average, 5·4 times per hour during the female's fertile period, compared with a mean of 0·3 times per hour for Violet-green Swallows. Nests need to be guarded against intruders intent on stealing nest material, destroying eggs, adding their own eggs, killing young nestlings, and taking over the site itself.

Conversely, once a male's mate has finished laying her own eggs, and is therefore no longer interested in extra-pair activities, he may go off to do some cuckolding himself. If he does not help with incubation, he has plenty of time in which to do this, but in

The mud-nest building hirundines use a unique construction technique, well illustrated by the nest being built by this pair of ***Northern House Martins****. First the pair find a suitable rough, vertical substrate, in this case the side of a building. Then they create a small projection by fixing mud pellets to the wall, thus forming the foundation for the eventual upward and outward growth of the final closed structure. Bouts of nest construction tend to take place in the morning, allowing each course to dry during the afternoon. Each layer is laboriously constructed from pellets of pure mud that are carefully worked into place with the bill to ensure that no air gaps weaken the structural integrity of the nest.*

[*Delichon urbicum urbicum*, Hortobágy National Park, Hungary. Photo: Günter Ziesler]

many hirundines the male does incubate to some extent. Given the opportunity, males may then reduce their parental care so that they can spend more time in pursuing other females. In Australia, for example, the male Fairy Martin (*Petrochelidon ariel*) takes a lesser share of incubation duties when there are plenty of fertile females available in the colony.

Pair-bonds often last only for the duration of the breeding season. Among resident species, however, the partners may stay together near the nest, roosting inside it, between breeding attempts. In the case of the migratory Barn Swallow, pair-members often breed together for more than one season if both survive, although unsuccessful pairs may split up. Purple Martins, in contrast, seem to form new pairs each year.

The nests themselves are in pre-existing holes, or in burrows excavated by the birds themselves, or are specially built structures of mud (see Systematics, Habitat). The hole-nesters exploit a remarkable variety of sites, including woodpecker holes in dead trees, termite nests, crevices in cliffs and caves, old burrows in riverbanks, ditches, road cuttings and quarries, holes in the roofs of buildings or in walls, chimneys, wells, crevices in streetlamps and traffic lights, pipes and nestboxes. The mud-nest builders also utilize a variety of substrates, such as trees, riverbanks, cliffs and caves, and many artificial structures such as bridges, culverts, wells, dams, mine shafts, and both the inside and the outside of buildings. The hirundines' flexibility in the sites that they use has resulted in some species nesting in unusual situations. Purple Martins, for instance, have nested in the moving arms of oil pumps and in a gourd fixed on the mast of a moving ship, and Barn Swallows have built nests on wasp nests, electricity wires, masonry bolts, nails and chains on walls, gear wheels and pulleys, picture frames, hats, pieces of cloth, lampshades and brackets, and even the corpse of an owl (Strigiformes).

Although sites of such a variety are serviceable, there are nevertheless several basic requirements for breeding purposes. As nest-sites need to be well protected from predators, they are typically high up, and often over water. Of 189 nests located in a study of Scottish Barn Swallows, 41% were 3-4·5 m above the ground, 38% were at 2-3 m, 16% were at over 4·5 m and only 5% were below 2 m. Mud nests are often built just below an overhang, again to deter predators, and also to provide shelter from inclement weather. Alternatively, in colonial species, they are frequently sited below an upper row of nests, often forming a honeycomb pattern. Caves, buildings and other dark places are often used, but probably for their inaccessibility and the protection that they offer from extremes of weather, rather than for the low light levels. In addition, a good source of wet mud is required for the building of mud nests, and a suitably rough substrate to which the material will adhere. The parents also need a clear flightpath to the nest entrance, for rapid access, and so they avoid dense vegetation. Moreover, they like to have a perch nearby on which to sing and preen.

For burrows, too, sites high up on banks are preferred, as these tend to be out of the way of predators and are less liable to collapse. Burrow-excavation is typically undertaken by both members of the pair, although it is started by the male, which arrives first. The birds use the bill to dislodge the earth, and then the wings and feet to remove it from the burrow, which is often 50-100 cm long. An enlarged cavity is made at the far end for the nest-chamber itself.

Similarly, mud nests are constructed by both partners. They start by fixing mud on to a vertical surface, creating a small projection, and then proceed outwards and upwards to form a cup or a closed or retort-shaped structure. In colonial species, the latter may allow pairs to nest close together, enjoying the benefits of living in a group, without the drawbacks of interacting with close neighbours and having intruders at the nest. Adjacent nests may also share a wall, thus reducing the time and energy invested in building. The shape of a mud nest often depends on where it is sited. Where South African Swallows use crevices, for example, they merely apply mud to reduce the size of the entrance and to create a tunnel. In North America, Cliff Swallows appropriate the burrows of Collared Sand Martins, known there as "Bank Swallows", in a similar manner. Among Cave Swallows in the south-west USA, open mud nests are usually built in natural cave sites and enclosed ones in artificial sites.

The birds collect mud as a pellet in the bill. They gather the material from a puddle or other suitable source, usually close to the nest-site, or they steal it from a neighbour's nest. When the bird applies the mud to the nest, it often vibrates its bill; this probably helps to disperse the wet mud into any air spaces, which would otherwise weaken the structure. A nest can contain over 1000 mud pellets. The majority of hirundines collect pure mud

*Together with its mate, this **Banded Martin** has completed the Herculean task of digging a nest burrow up to 90 cm long into a vertical bank. All that remains to finish the job off is to line the nest-chamber. Grass and other vegetation is picked up from the ground and moulded inside into a crude bowl. A final layer of feathers is often added and this provides important insulation for the eggs and young, especially during cold weather, when adults have to spend long periods away from the nest in order to collect adequate amounts of food. Discarded feathers are often caught in flight or grabbed from the surface of waterbodies, and they can be the cause of a great deal of competition and noisy squabbling.*

[*Riparia cincta xerica*, Xigera, Maun, Okavango Delta, Botswana. Photo: Peter Steyn/Ardea]

pellets, but the Montane Blue Swallow and the Black-and-rufous Swallow mix mud evenly with grass or rootlets and apply this mixture to the nest. Species in the genus *Hirundo* include vegetable fibres in the structure, whereas the species that make closed and retort-shaped nests generally construct these entirely with mud. Different types of nest are also composed of materials that differ in detail. In one study, it was found that Barn Swallows used mud with relatively more sand particles than that used by Cliff Swallows; sand may increase the strength of the nest and organic matter helps to bind the particles together, but they both make the mud less easy to work and so are less suitable for the more complex shape of the Cliff Swallow's nest. Cliff Swallows, given the choice of different muds, selected the one that was the most adhesive. Other material is sometimes incorporated. As an example, Cave Swallows nesting in caves where bats roost pick up both mud and guano from the cave floor.

Open cup-nests typically measure about 20 × 10 cm, with walls some 2-4 cm thick. The enclosed nest of the Northern House Martin measures approximately 18 × 10 cm and is 14 cm high, while the Red-rumped Swallow's retort-shaped nest is 18 × 18 cm, with a height of 10 cm, and with a tunnel 10 cm long. Nest dimensions of a given species can be quite variable, however, especially in tunnel length, that of Red-rumped Swallows ranging from 5 cm to 14 cm.

Within the burrow, hole or mud nest, the birds make a bowl of vegetable material, such as grass, dead leaves and twigs, collected from sites nearby or stolen from neighbours. Man-made substances, such as string, are sometimes incorporated, and even refrigerator insulation has been found in nests. Purple Martins begin by adding material to the floor of the cavity, after which they shape the bowl by spinning around and flattening the breast against the floor. They add fresh green leaves to the nest and mud to the base of the entrance hole, forming a wall between the hole and the nest. It is not clear why green leaves are added, but they possibly have an insecticidal function, helping to control ectoparasites. Some hirundines add a final lining of feathers, which can be important for insulation during incubation and the early nestling stage.

Nest-building can take several days to several weeks, with pairs arriving early often taking longer than do late-comers. The weather plays an important role, especially when wet mud is needed. Cliff Swallows also build more quickly if the nest abuts a neighbouring one and a wall is thus shared. Mud nests are often reused; in such cases, the birds may do no more than rebuild the rim or, if a tunnel is present, reconstruct that, and add a new lining. Nesting cavities and burrows are also sometimes reused. Old sites, however, are often avoided if they harbour parasites. Collared Sand Martins prefer to make new burrows in fresh banks each year, and will replace the old nest if they do reuse a burrow, while mud nests are sometimes left vacant for a season in order to eliminate parasites. Individuals will also switch to a different nest, or even a different site, after a failed nesting attempt. With Barn Swallows, and perhaps other hirundines, the male's nest-building activity is an indication of his potential investment in parenting, and females adjust the size of their clutch accordingly.

When cavities are scarce, hirundines often suffer competition for these nest-sites from other species, including other hirundines. Some usurpers can be thwarted: Purple Martins, for instance, are usually victorious in conflicts with Tree Swallows and Eastern Bluebirds (*Sialia sialis*). Others, especially House Sparrows (*Passer domesticus*) and Common Starlings (*Sturnus vulgaris*), are too aggressive and too persistent and eventually win the battle for ownership. Burrows are also attractive sites for other species, such as Swainson's Sparrow (*Passer swainsonii*), which has been seen to remove nestlings from the burrows of Plain Martins (*Riparia paludicola*) in East Africa. Mud nests, too, are sometimes usurped by other species, including, in the case of Cliff Swallow nests, Eastern Bluebirds, House Wrens (*Troglodytes aedon*), House Finches (*Carpodacus mexicanus*) and House Sparrows, the owners being evicted if the nest is active. In Africa, the White-rumped Swift (*Apus caffer*) frequently takes over the mud nests of swallows, such as the Rufous-chested Swallow (*Cecropis semirufa*), persistently attacking the nest if the owners are present or, if they are not, simply squatting and preventing their entry. Hirundines building nests on the same site, as do Barn and Cliff Swallows at times, also come into conflict, the Cliff Swallows being dominant in this example.

Hirundine eggs are generally white, as they do not need to be camouflaged inside a cavity. Some species that build a mud nest, however, have white eggs with reddish or grey/purple speckles or blotches, the markings usually concentrated at the broad end. This applies especially, but not solely, to those that construct an

*In **Pearl-breasted Swallows**, the task of incubating the eggs is undertaken by the female. This is fairly common amongst hirundines, although incubation is shared in some species. The clutch consists of two to four eggs, a single egg being laid each morning until the clutch is complete. Incubation lasts for 16-17 days, and the eggs hatch asynchronously over a period of days. As in many cavity-nesting birds, hirundine eggs are generally white. However some species, usually those which build open cup-nests, have coloured speckling on their eggs. In some species, opportunistic females attempt to increase their breeding success by dumping eggs in the nests of neighbouring females.*

open cup-nest. Species in the barn swallow group, the three *Ptyonoprogne* crag martins, the Wire-tailed Swallow, and the blue swallow and cliff swallow groups (see Systematics) have spotted eggs; the eggs of the two striped swallows in Africa, along with those of the more widespread Red-rumped Swallow and its close relatives the Striated (*Cecropis striolata*) and Rufous-bellied Swallows (*Cecropis badia*), are sometimes spotted. The amount and the pattern of spots can vary within a species. Eggs do not vary substantially in size. Among the smaller species, those of the Blue-and-white Swallow measure 17·2 × 12·5 mm and weigh 1·4 g, the corresponding figures for the eggs of the large Purple Martin being 24·3 × 17·4 mm and 4·1 g.

Many hirundines breeding in temperate regions lay a clutch of four or five eggs on average, with a typical range of three to six. Sometimes they lay as many as seven or eight eggs, or as few as one or two. It is not always possible, however, to know if very small or very large clutches are the complete clutches of a single female, because adverse weather can disrupt laying, and because females will dump eggs into the nests of their neighbours (see below). In the tropics, two or three eggs are usual. Clutch sizes of more widely distributed species tend to be smaller at lower latitudes. For example, Red-rumped Swallows breeding in southern Siberia lay five or six eggs, but their conspecific representatives in Africa lay only two or three. Hirundines, in common with many other birds, also exhibit a decline in clutch size as the breeding season progresses. Although this is partly because young birds tend both to lay late and to have small clutches, there is also a real decrease in clutch size during the season. For example, Barn Swallows in a study in Scotland averaged 4·9 eggs in their first clutch and 4·36 in their second. The seasonal decline may in part be related to changes in food abundance and in the length of daylight available for foraging; increasing numbers of parasites may also have an effect.

Eggs are laid early in the morning, at a rate of one daily, although bad weather, and hence poor foraging conditions, can interrupt laying for a day or more, or result in anomalously small eggs. The weather also has some effect on the quality and number of eggs, through its impact on the food supply. With Barn Swallows, the amount of lipid in the egg depends on the abundance of insects during egg formation, and the size of first clutches is also related to the ambient temperature just before laying. Hirundines also seem to be risk-averse, producing a brood of a size that the pair can rear in an average year, although experiments have shown that, in good conditions, they are capable of rearing larger broods than normal.

Among the more solitary species, the laying period within a local population can extend over several weeks. This is both because some individuals arrive later than others in the nesting area and because some will have a second brood. In the case of the colonial Cliff Swallow, however, pairs nesting together all lay at about the same time. In some populations, such as Cliff Swallows in south-east Arizona, laying may be synchronized because it needs to coincide with favourable weather, in this instance the summer monsoon. Brown and Brown suggested that, for the majority of Cliff Swallows, laying was synchronous for the simple reason that all pairs nested early in order to avoid the build-up of parasites in the nest later in the season.

Females of some hirundine species deposit some of their eggs in the nests of their neighbours. The extent of this brood-parasitism is not clear, but it varies between populations within a species. In one Purple Martin colony in Maryland, a third of nestlings in the nests of first-years were from eggs laid by another female, whereas a study in Texas found no evidence of such brood-parasitism. In Brown and Brown's study of Cliff Swallows in Nebraska, nearly a quarter of nests contained one or more eggs laid by neighbours; in another study, however, only about 4% of nests

*The exposed interior of this **Collared Sand Martin** burrow allows a rare view into its nest. The nest-chamber has been crudely lined by the female with grass, rootlets and other plant matter, as well as a large number of feathers. Typically, a clutch of 4-5 eggs is laid, the eggs hatching asynchronously after 12-16 days. Recently hatched nestlings, such as these, are rather feeble, almost totally naked, and with their eyes closed. Because they lack feathers, the nestlings are unable to maintain their own body temperatures and require continuous brooding for the first few days and occasionally thereafter, until they develop rudimentary plumage. After their eyes open at about nine days old, they become increasingly active and rush to greet incoming food-laden parents, ultimately crowding together at the burrow entrance.*

[*Riparia riparia riparia*, Woodbridge, Suffolk, England. Photo: Eric & David Hosking/FLPA]

*The strident begging calls of these young **Barn Swallows**, coupled with the strong visual signals of the yellow gape and prominent pale yellow bill flanges send a strong message to their parents. These youngsters are well feathered and therefore require little brooding, but they do need a regular supply of food, which is brought to the nest by both parents. In the early stages of brood-rearing the parents are also responsible for keeping the nest clean by removing egg-shell fragments and faecal material, the latter being swallowed or dropped away from the nest. Young Barn Swallows are attentive, quickly learning the calls of their parents, and after about nine days respond to alarm calls by keeping quiet and crouching low in the nest.*

were parasitized. DNA parentage tests of Barn Swallows and Collared Sand Martins have also revealed egg-dumping by extra-pair females that have mated with the male owner of the nest. Parasitic females either lay eggs directly in other nests or transfer them in the bill, and they sometimes destroy one of the host's eggs; they also rear a brood in their own nest. Such females may improve their breeding success by this behaviour or, by laying in more than one nest, they may reduce the chances of losing all their offspring in a poor season.

Whether pairs have one or two broods in a season varies both interspecifically and intraspecifically. Some species have just one brood, whereas others rear two or more. Cliff Swallows, for example, only rarely raise two broods, whereas Barn Swallows often produce two and sometimes three. An important determining factor is the length of the season, and, within a species, individuals that arrive early on the breeding grounds are more likely to raise more than one brood than are late arrivals. Second and third broods are also more common at low latitudes. On the other hand, reports of two or more broods being reared in a single nest are open to interpretation. Such cases could also involve either replacement clutches, when the first has been lost, or different sets of parents. Consequently, the number of breeding attempts made by pairs in a season is known for certain for only a few hirundine species, in cases where marked individuals have been followed over the course of a season.

Hirundine males show some of the highest levels of paternal care among passerines, in several cases sharing incubation duties with the female. In others, however, only the female incubates. There are also instances in which the roles played by the sexes differ from one subspecies to another. A good example is that of the Barn Swallow: the male of the North American race *erythrogaster* helps to incubate, although only to a small extent, but his Old World counterpart does not. Male Barn Swallows, unlike females, do not have a brood patch, while male Cliff Swallows, which do incubate regularly, have at most just a thinly feathered area or a few bare patches, which probably do little more than keep the eggs warm while the female is away. The male's contribution to incubation varies considerably; male Cliff Swallows, for example, incubate as much as do females, whereas male Collared Sand Martins in Scotland contribute about a third towards this process. Whether the male of a particular species helps may depend on how easily his mate can forage for herself. If the species' typical food supply is scarce or unpredictable, the female may not have the time both to incubate the eggs and to catch enough insects. Among some other avian species, the male brings food to his mate on the nest. This is not usual among hirundines, although it has been recorded on very rare occasions, as, for example, in the case of Eurasian Crag Martins.

Even if the male does not incubate, he may still sit on the eggs in the female's absence. Male Purple Martins do this, and can even be reluctant to relinquish the eggs when his partner returns from foraging. European Barn Swallow males, on the other hand, merely perch nearby and ignore the clutch. When the female alone incubates, she does so for about 70% of the daylight hours, more when the temperature drops and less in warm weather. Typically, incubation bouts last for 5-15 minutes and foraging periods away from the nest for just a few minutes, but, again, this depends on the temperature. Nevertheless, hirundine eggs can be quite tolerant of low temperatures and interruptions in incubation when adverse weather forces the parents to forage for hours at a time, rather than for minutes. The enclosed nests, the feather lining, the burrows and the sheltered indoor nest-sites of hirundines also help to maintain egg temperatures during inclement weather.

Associated with this division of labour is the timing of the start of incubation. When the male helps, incubation generally begins, at least intermittently, before the penultimate egg is laid, but it starts with the penultimate or last egg if he does not assist. This difference may be due to an inability of females to incubate unaided at the same time as they are producing eggs. On the other hand, different studies of one and the same species have reported different start times, perhaps suggesting some variability within species. In addition, females that incubate alone generally sit on the eggs for increasingly longer times during the laying period, possibly providing intermittent incubation. The clutches of most hirundine species appear to be incubated for about 14-18 days, the recorded range for the entire Hirundinidae family being 10-21 days. Because of the intermittent warming of the eggs during laying, however, it is often not clear when incubation has started. This

*This **Red-rumped Swallow** has been caught in the act of making a food delivery to its nestlings. Feeding young is an enormous task and at the peak of nestling development adults of this species have been recorded making as many as 138 food deliveries per day. Close examination reveals that this adult is carrying a small ball of food, consisting of compressed insects; this is either divided, between very young nestlings, or presented to just one, when the young are larger. Eggs hatch asynchronously and therefore the older, stronger nestlings naturally benefit by getting a larger share of the available food, with an increased chance of successfully fledging.*

[*Cecropis daurica rufula*, Spain.

Nature Picture Library]

makes calculation of the incubation period difficult, and values given in the literature may not always be accurate. Moreover, for a given species, the period can vary for a number of reasons, such as the presence of parasites in the nest in the case of the Barn Swallow, and reduced attentiveness in the case of the Fairy Martin.

The eggs usually hatch over one or two days, sometimes three. Tree Swallow eggs hatch more asynchronously in inclement weather, and for Barn Swallows the temporal spread increases at higher latitudes. Asynchronous hatching can be associated with substantial weight differences between nestlings in a brood. In Tree Swallow broods, for example, the largest nestling is on average 94% heavier than the smallest when the latter hatches. The earliest chicks to hatch are more likely to fledge.

On hatching, the nestlings are typically pink, with yellow inside the mouth and paler yellow or white on the bill-flanges. They usually have only scant tufts of white or grey down, principally on the head, wings and back, and the eyes are closed. The pin-feathers appear after a few days, and the primaries and tail feathers emerge from their sheaths at approximately 9-10 days. The eyes open gradually after about 5-6 days, and are fully open when the chick reaches 9-11 days. The nestlings are initially unable to regulate their own temperature, and they are brooded by either the female or both parents for the first few days, longer in bad weather than in good weather. Brooding is almost continuous for the first day or two, but decreases thereafter, ceasing altogether at about days 10-12, by which time the nestlings' feathers are breaking through and they are able to regulate their own body temperature.

Hirundines tend to grow slowly by comparison with other passerines. The most rapid growth occurs in the first week to 10 days, the nestlings reaching a peak in weight, greater than that of the adults, several days before they fledge, and then losing weight as a result of the maturing tissues losing water. Thus, the chicks of many species attain their highest weight at some 12-15 days, and those of Northern House Martins and the large *Progne* martins at 17-21 days. The nestlings often put on considerable amounts of fat, which tides them over during difficult periods. The amount of fat stored is related to the type of insects on which the species feeds and, therefore, the predictability or otherwise of the food supply. Northern House Martins, which feed on small swarming insects, are particularly likely to suffer from food shortages in bad weather (see Food and Feeding), but they are adapted to cope for short periods: the nestlings have sufficient fat reserves to last for a few days, and both nestlings and adults can become torpid in severe weather in order to save energy (see General Habits).

For their first few days of life, the chicks sprawl in the nest, raising the head to be fed. Their legs, wings and head grow rapidly during the first week or so, and they can then move and beg actively. Collared Sand Martin nestlings, brought up in burrows, begin to move forwards to meet the returning, food-carrying parents when about 9 days old, and at 15-17 days of age they wait at the burrow entrance. Barn Swallows, similarly, can hop up on to the rim of the nest by 14 days and preen themselves at 12-15 days. The fear response, crouching down in the nest when the parent gives an alarm call, develops at about 9 days.

Both hirundine parents feed the nestlings, often doing so about equally, and both are usually necessary for the successful rearing of the brood. In occasional polygynous matings, the second female is left to rear the brood alone. Female Tree Swallows, at least, are capable of achieving this at sites where food is abundant.

Each meal is a compressed ball, or bolus, of insects. With newly hatched nestlings, a parent may divide a food ball to feed more than one of them, but when the nestlings are older they feed one of them per visit. Small chicks may also be brought smaller and softer-bodied insects than those fed to older ones; the large *Progne* martins, in particular, deliver small flies and ants to young chicks, reserving dragonflies for older nestlings. Rates of 10-20 feeds per brood per hour would be typical, but feeding rates vary considerably, increasing with both the age and the size of the brood. Among colonial species, they also vary with colony size; some colonies may be too small for efficient social foraging, and in large groups the birds may compete for food. The main factor influencing feeding rates, however, is the weather. Scottish Barn Swallow parents will take only a minute or two to collect a meal of insects in good weather, but in poor conditions the average is six minutes and the parents are sometimes away for much longer. In turn, the weight of nestlings also varies with the weather and food abundance. Feeding rates gen-

Food provision is a non-stop task for the parents of these young ***White-throated Swallows****. Young hirundines lay down fat reserves during periods of food abundance and these can be important, both during the nesting phase and after fledging, when individuals may face temporary food shortages caused by inclement weather. If periods of bad weather persist, adults and young can enter a state of torpor to save energy while waiting for more favourable conditions to return. In exceptional conditions large numbers of birds can die during the breeding season, if successful foraging is hampered by cold or wet weather.*

[*Hirundo albigularis*. Photo: J. J. Brooks/ Photo Access]

erally increase as the brood grows, and then level off when the chicks reach peak weight, and decline slightly before they fledge. Very rarely, individuals other than the parents have been recorded as feeding the nestlings, as documented, for example, at nests of Barn Swallows and Welcome Swallows. These may be first-brood fledglings feeding their second-brood siblings, or unmated individuals that are unrelated to the nesting pair.

Nest sanitation is at first the responsibility of the parents, which remove the eggshells, dropping them well away from the nest, and consume or remove the faecal sacs of the young nestlings. After a week or so the nestlings begin to defecate over the rim of the nest, and by the age of about 12 days they deposit the majority of faecal sacs below the nest. Collared Sand Martin nestlings deposit their faecal sacs outside the burrow from about 14 days.

Both parents defend the eggs and nestlings from predators. Hirundines will join together in a group to mob birds of prey and other predators, but solitary and colonial species differ in their degree of participation. The more solitary Barn Swallows and Purple Martins emit alarm calls and dive at a predator that is close to their own nest, but they do not do so as a co-operative group. Other pairs circle or perch at a safe distance. Barn Swallows are particularly daring, approaching close to the predator and sometimes even hitting it. With the highly gregarious Cliff Swallow, in contrast, the birds in a colony gather above a predator and give alarm calls, but they do not dive at it.

As the fledging time approaches, the parents may begin to entice their brood out of the nest by means of contact calls or a more elaborate display. Northern House Martins start to do so when the nestlings are 19-24 days old, by flying slowly past the nest or hovering in front of it, perching nearby and calling, without offering any food. Eventually, the nestlings will follow a parent away from the nest, exchanging contact calls. It can take more than a day for the entire brood to leave the nest, and fledglings frequently return to it during the day, sometimes for several days, as well as roosting there. As a consequence, it can be difficult to calculate for how long the chicks stay in the nest. Further, growth rates and the nestling period can also vary with the weather, the abundance of food and the presence of parasites. With Barn Swallows, for example, the presence of mites (Acarina) in the nest can hasten fledging, but blowfly (Calliphoridae) larvae appear to reduce the nestlings' growth rate and delay fledging. For many hirundines, development from hatching to fledging takes about three weeks, while the large New World martins and the Northern House Martin require four weeks.

The parents typically feed their fledglings for several days. Those of the more solitary species generally move the brood to a secluded perch, such as a branch or wire, where they visit them with food. In contrast, the young of colonial species form crèches, which may be 2-3 km from the nest-site and contain hundreds of fledglings from several local colonies; parents recognize their own offspring in these crèches by their unique calls (see Voice). For the first few days, Barn Swallows perch beside their young in order to feed them, but later they often hover above the perch and the youngster flies up to take the food. Cliff Swallows transfer food to the fledgling's bill while in flight, or drop it for the young to catch.

Fledglings, often escorted by their parents, frequently return to the nest to roost for several nights. They begin to forage for themselves after four or five days, and become independent after a week to ten days. The family may then break up and the fledglings wander more widely, but this is not always what happens. Parents and young of Barn Swallows have been known to stay together for several weeks, and there are records of juveniles being fed by adults on migration, suggesting the existence of long-term bonds. In one particularly interesting case, a fledgling Welcome Swallow continued to roost in the nest while its mother laid and incubated her second clutch. Juveniles of the Cliff Swallow tend to keep in flocks with their peers, but both they and young Barn Swallows will visit other nest-sites and enter nests containing chicks, where they are fed by the nest-owners, which may not yet have learnt to recognize their own offspring. Barn Swallow fledglings have been recorded as visiting nests and breeding groups 5-8 km from their natal one, and juvenile Cliff Swallows have been found at colonies up to 60 km from the one at which they hatched. Juvenile Collared Sand Martins, too, are known to wander widely before migrating. These movements may allow the young birds to assess potential breeding sites and to familiarize themselves with local landmarks in preparation for their return in the following year (see Movements).

Hatching success for hirundine species breeding at high latitudes is often 90% or more. Fledging success is more variable,

*For tropical hirundines, such as the **Black Saw-wing**, rearing young to fledging is far from guaranteed. Clutch and brood losses appear to be much higher for tropical hirundines than for their more productive temperate counterparts. Presumably young Black Saw-wings enjoy higher survival rates during their first year than do temperate species that have to face the perils of a long and arduous migration to and from the wintering grounds. Species limits are uncertain across the large sub-Saharan range of the Black Saw-wing.*

[*Psalidoprocne pristoptera holomelas*, Somerset West, Western Cape, South Africa. Photo: Nico Myburgh]

depending, for example, on the weather conditions and the abundance of parasites, but it is often about 60-80%. In six studies of Purple Martins, 50-85% of eggs laid produced fledglings, with averages of 2·3-4·2 per pair. In one of these studies, however, in one year when the weather was cold and wet, only 18% did so, producing an average of only 1·2 fledglings per pair. Productivity varies considerably both from year to year and from one pair to another; a pair of Barn Swallows, for instance, can rear no young at all in a season or as many as 16. Tropical hirundines are less well studied, but they seem to suffer greater losses of clutches and broods. The fledging success of Pacific Swallows in one study, for example, was as low as 38%.

Hirundines are well prepared for short periods of bad weather and food scarcity. Cliff Swallow eggs, for example, can still hatch after several hours, and even a few days, of cold weather. As mentioned above, hirundine chicks have fat reserves, and nestling starvation is a significant cause of mortality only when the food shortage lasts for more than a few days or is combined with a high incidence of parasites in the nest. In a study of Barn Swallows at Cranberry Lake, in New York State, for example, the majority of first broods were lost during a period of cold, wet weather. Occasionally, local populations may even be wiped out, as happened to Purple Martins in the north-east USA in June 1972 as the result of a hurricane. Drought also limits the availability of insects, as well as of water, and affects the breeding performance of, for example, Cave Swallows in Texas. Some effects of the weather are more direct. Mud nests can be destroyed if soaked by rain or desiccated in hot, dry weather, and nestlings may also die if temperatures are too high.

For adults, weather-related starvation can be the main mortality factor during both the breeding and the non-breeding seasons. Drought in the wintering areas, with the concomitant loss of the food supply, may be responsible for the majority of deaths of adult Barn Swallows breeding in Europe, while cold weather in the spring may be an important mortality factor in parts of North America. Extreme weather may also select for birds with particular characteristics. In a six-day period of cold, wet weather in May, on the breeding grounds in the Great Plains of North America, it was generally the larger Barn and Cliff Swallows, having the least asymmetrical wings and tails, that survived. In a similar context, it is interesting to note that a decrease in body size of British-breeding Collared Sand Martins was recorded following a drought in the birds' wintering area in the African Sahel zone in 1983/84. For birds on migration, too, cold or stormy weather can be fatal, and hundreds of thousands of hirundines have been killed in some severe cases.

As mentioned several times in the preceding paragraphs, hirundines and their nests harbour a wide variety of blood-sucking and other parasites, some of which have highly deleterious effects on several aspects of the birds' breeding biology. Since hirundines avoid heavily infested nests, the presence of parasites can delay breeding by forcing them to build a new nest, instead of reusing an existing one. The parents may then not have time to produce a second brood. Parasites can also affect incubation time, the nestlings' health (compromising their immune response, the length of the nestling period, and survival after fledging), and adult survival. In some cases, the parasites reduce the growth rate of the nestlings; in others, their effect is more severe, leading to nestlings dying, perhaps directly from loss of blood or, in some instances, from the combined effects of parasites and food shortages. In particular, blowfly larvae, swallow bugs (*Oeciacus*), ticks, mites and fleas (Siphonaptera) are responsible for reduced growth and, sometimes, deaths of nestlings. In an experiment in which he manipulated the numbers of mites in nests, Møller found that 15-day-old Barn Swallows in nests infested with mites weighed about 5% less than did those in fumigated, mite-free nests. Fleas reduced the weights of Collared Sand Martin chicks by a similar amount. Swallow bugs are the main cause of nestling deaths for Cliff Swallows, especially those in large colonies and those breeding late in the season. Brown and Brown also found a difference in weight of up to 15% between parasitized and non-parasitized Cliff Swallow nestlings. In addition, swallow bugs transmit a virus to Cliff Swallows, and this, too, is more prevalent in large colonies. Other parasites of hirundines include hippoboscid flies, dermestid beetles, lice, nematodes, cestodes, trematodes and protozoans.

Although some swallows and martins do fall victim to birds of prey, in particular falcons (*Falco*), predation is not usually severe, especially for adults during the breeding season. Occasionally, however, an individual predator can have a large impact on a breeding group, and one bull snake (*Pituophis catenifer*) took some 150 eggs from a Cliff Swallow colony in only three days. Predators of hirundines include, besides raptors and snakes, owls, magpies (*Pica*), grackles (*Quiscalus*), woodpeckers, racoons (*Procyon*), squirrels (Sciuridae), rats (*Rattus*), weasels (*Mustela*) and cats. Some predators, such as grackles, pull chicks out of nests, and woodpeckers have been known to drill into mud nests in order to reach the contents. Opportunistic predation by Marabous (*Leptoptilos crumeniferus*) has also been recorded in Kenya, where dense flocks of Barn Swallows were feeding very low above the ground at Ngulia Lodge; the storks quickly lunged at and, occasionally, caught and consumed any swallows that flew too close to them.

Fire ants (*Solenopsis invicta*) also destroy eggs and nestlings, in one colony depredating a quarter of nests. In addition, some eggs and nestlings are lost when other species, such as Common Starlings and House Sparrows, or deer mice (*Peromyscus*), try to take over the nest-site. Infanticide also accounts for some deaths: in one study of Barn Swallows, 32% of deaths of nestlings over a five-year period were attributed to this cause.

The majority of individual hirundines start to breed when one year old and continue for only a few years, but some reach 8-9 years or more. Maximum lifespans are 12 years for Cliff Swallows and Tree Swallows, 13 years 9 months for Purple Martins, 14 years 6 months for Northern House Martins and nearly 16 years for Barn Swallows. Mortality tends to be highest in the first year. For example, annual survival rates in one study of Cliff Swallows were 57% for adults and 17% for first-years. Survival does, however, vary from one year to another, the annual rates for adult Cliff Swallows ranging from 47% to 64%, with survival better when summer temperatures are high and, in addition, rising with increasing colony size. For Barn Swallows and Collared Sand Martins, it varies in accordance with the weather in the winter quarters. Survival also depends on other factors, such as an individual's condition, quality and breeding effort. In the case of Barn Swallows, long-tailed males survive better than do short-tailed ones, and the number of nestlings reared can affect female survival.

Movements

Swallows and martins breeding in temperate regions generally migrate to warmer areas for the non-breeding season. Although their insect prey is abundant in spring and summer, it crashes with the low temperatures of winter, forcing the birds to move to regions where insects are still available. Barn Swallows from northern Europe, for example, migrate to Africa, and those from North America fly to South America. At lower latitudes, hirundines are often resident or make only short post-breeding movements, sometimes descending to lower altitudes. Some species breeding within Africa are migratory only in certain areas. One of these is the Lesser Striped Swallow, which is resident near the equator but migratory to the north and south of it. In some areas, hirundines are partial migrants, as typified by the Welcome Swallow: some Welcome Swallows are present all year in southern Australia, but there is also an influx of birds into northern areas after the breeding season in the south.

Hirundines migrate by day, often flying low down and feeding as they go. They move in loose flocks, sometimes containing hundreds or thousands of individuals. These can be seen throughout the day, but juvenile Barn Swallows tend to start earlier and finish later in the day than adults. Routes taken are usually over land or along coastlines with only short water crossings, but some Purple Martins and Barn Swallows in North America, for example, travel via the Gulf of Mexico and the Caribbean Sea. Individuals of some species are known to return to the same wintering site each year and generally remain in the same area throughout the non-breeding season, but wintering ranges can change. In the early 1960s, after a drought in northern South Africa combined with wet weather in the Karoo, Barn Swallows in southern Africa extended their winter range farther south and west.

Both autumn and spring migrations are staggered, and the timing of each often varies from year to year. The migration in autumn is leisurely and can take several months. Barn Swallows in Britain, for example, gradually travel southwards, moving from one roost to the next, and staying for a number of days at each site. They appear to proceed more quickly as autumn progresses, probably by spending less time at each stop and wandering less. In spring, however, individuals, especially adult males, usually move more quickly, in order to acquire a nest-site before the competition arrives. Migration can be accomplished very quickly: there are records for Barn Swallows covering a distance of 12,000 km in 34 days, a daily average of about 320 km, and travelling 3028 km in 7 days, which is the equivalent of 433 km per day.

The proportion of first-year individuals that return to breed at the place where they hatched varies, but these young birds tend to return to the same general area, although not necessarily to the same site. Moreover, males have a tendency to return to localities closer to the natal site than those to which females return. In contrast, older individuals frequently come back to the breeding site, and often to the nest, that they used in the previous season, especially if they were successful there. A large amount of the data on site-fidelity, however, is difficult to interpret, because it is not possible to distinguish between dispersal and mortality as the reason for an individual's absence. In addition, the pattern of dispersal will in many cases reflect the distribution of observers.

*Young **Collared Sand Martins** are encouraged to leave the nest by their parents, which perch close to the nest entrance and call repeatedly to entice them out. After taking their first flight, young birds frequently return to the nest, which they may continue to occupy for a number of days, as it provides a safe roosting location. As soon as the young become independent the adults join large communal roosts, and within a short time start their migration south to the wintering grounds. The youngsters however hang back and drift around, moving between roosts, perhaps learning the lie of the land, before they too finally migrate to the winter quarters.*

[*Riparia riparia riparia*, Burgos, Spain. Photo: José Luis Gómez de Francisco]

*Fledgling **Wire-tailed Swallows**, like all young hirundines, remain heavily dependent on their parents for a number of days after they leave the nest. In common with other solitary hirundines, the parents entice the young birds out to a suitable, safe perch, which they regularly visit with food. At first, the young are presented with food by perched adults, as illustrated here, but later on the parents encourage their young to fly and receive offerings. After 7-10 days, the young learn to fend for themselves, and become independent. Colonial species behave similarly but gather their young into large crèches and, unlike the solitary species, are able to identify the calls of their own young, in order to find and feed them.*

[*Hirundo smithii smithii*, Kruger National Park, South Africa. Photo: Rolf Kunz]

Juvenile Cliff Swallows are among the more philopatric of hirundines. Of those ringed in the year of hatching and recaptured in the following year, 48-74% returned to the natal site in three studies; others were found mostly up to 3·5 km away, and some as far as 77 km from the hatching site. In contrast, only 1% of ringed Purple Martin nestlings in a study in north Texas, and 5% in Ohio, returned to the natal site to breed. Similarly, 0-4% of Barn Swallow nestlings returned to the locality in the following year, with more males than females doing so. Of adult Cliff Swallows caught in one year, 45-82% bred at the same site as in the previous year, while adult Barn Swallows are highly faithful to their breeding site, almost 100% returning to it in subsequent seasons.

Hirundines are often recorded in places outside their normal range, sometimes as rare vagrants but at other times more frequently. In several instances, such phenomena have led to eventual expansion of the breeding range. Welcome Swallows from Australia, for example, had been recorded in New Zealand since the 1920s and started to breed there in 1958. Since then, the species has become a widespread and common breeding bird, both on the two main islands and on smaller offshore islands. In the New World, Cave Swallows have occurred as vagrants as far north as Nova Scotia, on the eastern Atlantic coast, and it is interesting to note that this largely Middle American species has, over the last hundred years or so, expanded its breeding and non-breeding ranges northwards into southern North America. In Europe, the Red-rumped Swallow and the Eurasian Crag Martin have also moved north in the last century, both as vagrants and as breeding birds.

Long-distance, transoceanic vagrancy is also recorded on rare occasions. Both the Tree Swallow and the Cliff Swallow, for instance, have been observed on a handful of occasions in Europe.

Relationship with Man

Hirundines have a long association with humans, some species having nested on artificial sites for hundreds or, in some cases, even thousands of years. There are Danish subfossil finds 5000 years old from Neolithic flint mines, and the Roman poet Virgil wrote of a swallow, presumably the Barn Swallow, nesting in the rafters of a house. Having nested close to people for so long, the Barn Swallow, not surprisingly, features in many legends and customs, nearly always as a virtuous bird. It is the quintessential harbinger of spring, enshrined in the proverb "One swallow does not make a summer", and its arrival is associated with several customs. In Bohemian folklore, for example, unmarried women who see a pair of swallows will marry in that year, although single men need see only one swallow in order to acquire a bride.

Because they arrive back in Europe at about Easter time in the Christian calendar, Barn Swallows have become associated with the Crucifixion of Christ. Various legends tell of how they attempted to lead astray those coming to arrest Jesus Christ in the Garden of Gethsemane, of how they tried to remove His crown of thorns, or the nails from the cross, to wipe the blood from His wounds, and to console Him. In another, magpies pricked Christ's feet with thorns, while the swallows removed them, with the result that swallows were granted safe lodging in people's homes. The swallows' role in helping humans, however, extends farther back than this, and across many more cultures and religions. A swallow is said to have reunited Adam and Eve after their expulsion from Eden, and Noah is alleged to have released a swallow after the Flood to signify a new era. Swallows are mentioned in the *Koran* as attacking Christians who were besieging Mecca. In both European and Asian mythology, swallows stole fire from the gods and brought it to humans on earth, losing the middle tail feathers in the process. Different legends claim that "Tengri the Sky Being" struck the tail with an arrow, or that the Devil burnt it with a firebrand, marking the throat and forehead red, too, or that sparrows which were supposed to be guarding the fire pecked out the tail. Alternatively, the Snake in Eden is said to have bitten it out, or Thor tore the tail with a thunderbolt. In Russian mythology swallows are spirits of dead children, and in parts of Africa they are messengers sent from deceased ancestors to bring comfort to the living.

Goddesses have been transformed into swallows on several occasions. Athene became one in order to remain hidden when her suitors were killed, and Isis fluttered as a swallow over the resting place of her husband Osiris. Another relevant story concerns the Greek Tereus, who fell in love with Philomena, the sister of his wife Procne, raped her and cut out her tongue in order to stop her telling on him, but she managed to inform her sister and the two ran off together. They asked the gods to save them from Tereus and were turned into a swallow and a nightin-

gale (*Luscinia*), respectively. Without her tongue, Philomena, the swallow, can now only twitter. In an alternative version of the legend, it was Procne who became the swallow, and her name is now the basis of the scientific generic name for the American martins, *Progne*. In ancient Egypt, the swallow was a minor deity, and was often mummified.

Swallows are usually viewed as good omens. A widespread belief is that a pair nesting in the house brings good luck, and people in China even put up ledges inside their houses to encourage the birds to nest. Destroying a swallow or its nest, however, attracts misfortune, such as that cows will produce bloody milk, or none at all, or that lightning will strike the house. Nevertheless, swallows are sometimes considered a bad omen, foretelling a death, or even a disaster, as, for example, those nesting on Cleopatra's flagship before the Battle of Actium.

Barn Swallows also feature in a number of folk remedies from both Europe and Asia. On the principle of curing like with like, this species, with its twittering song, has been used in cures for speech impediments, as well as for such other ailments as epilepsy, headaches, and eye and kidney problems. The heart of a swallow, eaten or hung in a bag around the neck, was thought to improve a person's memory. A European legend concerns a "swallow stone", said by Pliny to be found in the stomach of the oldest nestling in a brood of swallows, which could cure blindness, epilepsy and slurred speech. There are many versions of the story, one being that the female swallow, if one blinds her nestlings, will bring the stone to the nest in order to cure them. In some versions, there are three stones of different colours and with different properties, such as that of making the owner of the stone fairer or more attractive to a lover, that of providing protection from danger, or that of improving memory.

The involvement of hirundines with humans in the Americas is less well known. One species, at least, the Purple Martin, had some spiritual or ceremonial significance to the Omaha Indians who lived in Nebraska: six bodies of these birds were part of the Sacred War Pact kept in the Tent of War. In addition, in the southeastern part of the United States, natives ground up the bodies of Purple Martins and Belted Kingfishers (*Megaceryle alcyon*) and placed the powder on their pelts before overwinter storage, although it is not known whether the powder acted as an insecticide. Barn Swallows are known to have been nesting in native American settlements in the early 1800s, and probably long before that. In Mexico, Cave Swallows nest in Mayan ruins on the Yucatán Peninsula, and perhaps elsewhere; it is not known how long ago this habit developed, but it may have facilitated the species' move to modern buildings, bridges and culverts.

In the nineteenth century, Barn Swallow feathers were used in the millinery trade. Concern over this led indirectly to the founding of the American Audubon Society and, thus, to the early stages of the conservation movement. In some places, especially in Africa and Asia, swallows and martins have been, and sometimes still are, caught for food, and nestling Collared Sand Martin chicks have even been used as bait by fishermen (see also Status and Conservation).

People usually welcome swallows and martins when they nest in or on their houses and other buildings. In the past, the birds and their nests have also been protected by superstition. In most cases, the hirundines are allowed to nest where they will, and doors or windows may even be left open so as to provide an entrance for them. Only a few species, however, are actively encouraged by the erection of nestboxes (see Status and Conservation). One particularly noteworthy example is the Purple Martin, which has become a regular garden-breeding bird in both town and country; indeed, its popularity in eastern North America has given rise to a whole industry of bird-house construction, as well as two organizations devoted to the species. Native Americans first attracted Purple Martins by putting up hollowed-out gourds as nesting sites for them; the martins may have provided a warning of the approach of predators, as well as perhaps feeding on unwelcome insects. The birds soon started to use nest-sites provided by European settlers, and in the eastern part of the range they now rarely use natural ones. Manufacturers of the bird houses claim that the Purple Martins will eat large numbers of mosquitoes, but there is no evidence that they do.

*Hirundines, such as **Tree Swallows**, that utilise temperate regions during the breeding season are forced to be migratory. They avoid the impossible foraging conditions during the temperate winter by moving sometimes enormous distances to more equable and food-rich tropical and subtropical regions. Tree Swallows, for example, breed in north and central North America and migrate to winter quarters along the southern coast of the USA, the Caribbean and the coastlines of Central America and northern South America. Huge flocks assemble at post-breeding roosts and eventually the birds start to move south during the day, staying in loose flocks that feed in transit and come together each evening at a new roost, until they finally reach their wintering grounds. The distance covered per day during migration tends to vary seasonally.*

[*Tachycineta bicolor*, Florida, USA. Photo: Roland Seitre]

*Over large parts of its range the **Purple Martin** has a unique relationship with man and only uses artificial nestboxes specifically provided for it. Native Americans first encouraged this habit by hanging hollowed out gourds in their villages and many of today's artificial nests still resemble the early prototype, albeit mimicked in modern materials. It is not surprising that swallows and martins are so popular, as many people around the world live in close proximity to these birds, even sharing their homes with them, while for those people living in temperate latitudes there are few more rapturously received migrants after a long winter. Hirundines in such situations are true harbingers of the warmer summer days to come.*

[*Progne subis subis*, Burr Ridge, Illinois, USA. Photos: Rob Curtis/ The Early Birder

Hirundines are not usually considered to be pest species, but they are sometimes a nuisance. Some people object to the faeces that accumulate at such breeding sites as porches and garages, and they destroy the nests, although the problem can often be solved by simply putting up a board or sheet beneath the nest. Roosts on building ledges or on wires or trees in towns can be a more serious problem, and not just because of the birds' faeces. At a site in Mexico, for example, Purple Martin roosts are so large that they cause the electric wires to break, and people consequently kill the birds.

It is difficult to estimate the beneficial effects that swallows and martins may have in terms of their influence on the human environment. They certainly take huge numbers of insects, especially when provisioning nestlings, and they will often feed on temporary concentrations of prey, which may be useful to their human neighbours during an infestation of a pest species. There is no doubt that they take many injurious species. Barn Swallows in the USA, for example, have been recorded as eating cotton boll (*Anthonomus grandis*) and rice weevils (*Sitophilus oryzae*), codlin moths (*Cydia pomonella*) and cutworm moths (*Agrotis*). Their true value in controlling pest species, however, is not known. The good that they do may also be countered, at least in part, by their consumption of beneficial insects.

Relatively recently, hirundines, especially Tree Swallows, have been investigated as possible biomarkers of the presence of pollutants, which can accumulate along a food chain from insects to insect-eaters. While a single insect may contain a small amount of a pollutant, a swallow, eating large numbers of the insect, can build up a high concentration. The biological effects of pollutants and contaminants in an area, such as an old mining site, will be reflected in the hirundines foraging on the insects at that locality.

Status and Conservation

Of the 83 species of Hirundinidae currently recognized, five are considered to be globally threatened. A further four are listed as Data-deficient, a reflection of the lack of knowledge of the biology of many species in this family.

The conservation status of one hirundinid species is Critical. The White-eyed River Martin, first discovered as recently as 1968, at a single roost-site in Thailand, is known from only a few specimens and sightings, but it may already be extinct. Numbers of hirundines present at the roost have decreased dramatically because of habitat loss and trapping for food, and this species has not been seen since an unconfirmed report in 1986. Its breeding range and habitat requirements are unknown, although it may nest on sandbars along forested rivers, as does its sole congener, the African River Martin. Surveys along potentially suitable rivers in north Thailand and north Laos, however, have not provided any signs of the species. Likely breeding areas have been drastically affected by deforestation, the damming of rivers, and the spread of intensive agriculture and human settlement, as well as by direct disturbance in the form of hunting, fishing and sand-dredging. These activities have reduced the numbers of riverine birds in general, and perhaps, therefore, those of the White-eyed River Martin, too.

In the Caribbean, both the Bahama Swallow and the Golden Swallow have small and fragmented breeding ranges and declining populations, and both are regarded as Vulnerable. The Bahama Swallow, having a total population estimated at 2400 pairs in the late 1980s, not only faces the threat of habitat loss through logging and housing development, but also suffers severe competition for nest-sites from introduced House Sparrows and Common Starlings. It may have already ceased to breed on New Providence. Previous logging of its pine-forest habitat has probably greatly reduced the number of available breeding sites in the Bahamas; although logging is not currently being carried out, the secondary forest is now close to the stage at which such operations may be started again. One potential method of helping to conserve hirundines is to put up nestboxes as alternative nest-sites, as many species will take to these (see below). A nestbox scheme on Grand Bahama in 1995, however, was unsuccessful, with 227 boxes attracting only three pairs to breed.

Farther south in the Caribbean, the Golden Swallow, occurring on Jamaica and Hispaniola, has also lost its forest habitat to agricultural expansion. Once common, it has declined dramatically in numbers since the late nineteenth century, and its global population is now estimated to be in the range of 2500-10,000 individuals. On Hispaniola, its forest habitat has been whittled away by the practice of shifting agriculture, and this loss of habitat is likely to be involved in the species' decline on Jamaica, from where few recent records are known. Unlike the Bahama Swallow, the Golden Swallow seems to be subject to only little competition for nest-sites with the introduced Common Starling, which nests at lower elevations.

Two Afrotropical swallows are also listed as Vulnerable. The Montane Blue Swallow, which has a small population, estimated at about 2000 pairs in 1998, is an intra-African migrant that spends both the breeding and the non-breeding seasons in grassland. This habitat is threatened by afforestation, cultivation, livestock grazing and burning, and also by the invasion of non-native wattle (*Acacia*), pine and bracken (*Pteridium*); small-scale mining is a further potential threat. These encroachments on the species' habitat are thought to be responsible for the population decline, and they continue to give cause for concern.

The White-tailed Swallow, breeding within a very small range of less than 15,000 km^2 around Mega and Yavello, in southern Ethiopia, appears also to be at risk because of clearance of its bush habitat for grazing. Only low numbers of this swallow have been recorded in recent surveys. The species is poorly known, however, and there is an urgent need for additional, reliable data on its population size and its response to habitat change.

The African River Martin, Brazza's Martin, the Sinaloa Martin and the Red Sea Swallow (*Petrochelidon perdita*) are placed in the conservation category of Data-deficient, as they are too poorly known to be categorized more precisely. The first three appear to have limited distributions, with their population sizes inadequately known. The African River Martin occurs in Gabon, PRCongo and DRCongo and may be quite common, if local. Colonies of up to about 800 birds have been recorded, and large flocks on migration have included one of about 15,000 individuals. Nevertheless, very little information is available on the biology of this species, and recent discoveries of colonies in Gabon and PRCongo emphasize our lack of basic knowledge of its range. Brazza's Martin also breeds in central PRCongo and southern parts of DRCongo, as well as in the extreme north of Angola, but it is found in only small groups and hardly anything is known about its biology or current status. Both the African River Martin and Brazza's Martin are probably subject to a degree of human predation.

In America, the Sinaloa Martin, which is sometimes treated as a subspecies of the Caribbean Martin, breeds at just nine sites in the Sierra Madre Occidental, in western Mexico. Its wintering areas are not known, but observations of the species on the Pacific coast, and farther south, suggest that they may possibly lie in South America. Irrespective of whether this is a full species or a race of the Caribbean Martin, its small range justifies the concern about its conservation status.

The Red Sea Swallow is even more enigmatic. It is known from just a single specimen, found dead at Sanganeb lighthouse, off the coast of Sudan, in May 1984, and, possibly, a few sightings. Just before this type specimen was obtained, two swallows, perhaps of the same species, were seen as they flew over the Red Sea towards Jedda. The whereabouts of this swallow's breeding quarters are a mystery; it has been suggested that they may be in the Red Sea hills of Sudan or Eritrea, or along the coastal hills of western Saudi Arabia. Otherwise, several cliff swallows have been recorded in Ethiopia, including about 20 at Lake Langano, 3-8 in Awash National Park and, recently, others at a further three sites. Although it has been thought that these Ethiopian birds could be Red Sea Swallows, some observers believe that they may well be of a different and, as yet, undescribed hirundine species.

Apart from the above-mentioned species, the Mountain Saw-wing may also be of concern. It occupies an exceedingly small range in western Africa, being confined to Mount Cameroon, in west Cameroon, and the nearby island of Bioko. It appears, however, to be quite common within this tiny range, where it occurs in a variety of habitats, and it may not be under any immediate threats. Nevertheless, this situation could change, and any adverse modification of these habitats could easily put the Mountain Saw-wing at risk.

Other species of hirundine generally have more healthy populations, and some are extremely common and widespread. Even so, they can be subject to local threats, such as habitat loss. Some species are on local Red Lists. One example is the Purple Martin in British Columbia, although this population is increasing as a result of the provision of nestboxes (see below). In addition, the Barn Swallow and the Collared Sand Martin are listed as species of European conservation concern because of widespread declines in their populations.

*The stunning **Montane Blue Swallow** is one of five hirundine species listed as globally threatened. It is a migratory African species which has a small, declining population, which during the breeding season is totally dependent on montane grassland. Throughout its disjunct range such habitat is under threat from plantation forestry, cultivation, overgrazing, fire and the invasion of alien plant species. In addition to these problems, Montane Blue Swallows also occur at naturally low densities and have rather fussy nesting-cavity requirements.*

[*Hirundo atrocaerulea*, Kaapse Hoop, Mpumulanga, South Africa. Photo: Geoff McIlleron/ Firefly Images]

Where populations are threatened, this is due mainly to habitat loss and degradation but, on a local level, a variety of other factors, such as disturbance, nest-site competition, pollution and pesticide usage, and extreme weather conditions, may be involved. All of the five globally threatened species mentioned above have been affected by a reduction in suitable habitat, as a result, for example, of logging of forest or clearance of bush and grassland for conversion to grazing or other uses.

Competition for nest-sites can have a serious impact on local populations, as is the case for the Vulnerable Bahama Swallow. Human activity often makes this competition more severe, not only through the removal of trees and other suitable sites but also through the introducing of competitors such as House Sparrows and Common Starlings. These species' aggressiveness and persistence allow them to usurp holes and drive away hirundines. In addition to chasing the latter, they also stuff vegetation into the hole, thereby preventing other birds from using them, and throw out any eggs or small nestlings that are already present. In one study of Barn Swallows, House Sparrows reduced the fledging success of the population by 45%. These introduced species may have been involved in declines in Purple Martin and Cliff Swallow populations since the nineteenth century. In Poland, competition with House Sparrows is thought to have driven Northern House Martins to change their nest-sites from the outside to the inside of buildings.

The threats to hirundines are mainly incidental to human activity, but direct persecution is also evident. Large numbers of both adult and nestling African River Martins are taken by hunters in DRCongo, and hirundines are caught at winter roosts in Africa, Asia and probably South America, this human pressure having contributed, for example, to the probable extinction of the White-eyed River Martin in South-east Asia. In Europe, hundreds of thousands of migrating hirundines, along with many other species, have also fallen victim to hunters, especially in Malta, in a single year. While some birds are taken for food, or for sale in the local markets, many are shot merely for target practice. Roosts are also vulnerable to incidental poisoning by avicides used to control seed-eating pest species. Historically, too, there are cases of people killing hirundines for particular purposes, such as nestling Collared Sand Martins being taken for fishing bait and Barn Swallows being used in medicines (see Relationship with Man).

The close association of many hirundines with humans also results in frequent accidental deaths. Those species nesting on bridges and in culverts, in particular, are sometimes hit by vehicles. Deaths resulting from flying against or hitting buildings, windows and wires are less common, but they do occur. Juveniles are most vulnerable to these types of accident.

Pesticides and other pollutants in insects can affect their predators, such as hirundines. Tree Swallows have exhibited such biochemical effects as inhibition of cholinesterase, although this is not always reflected in reduced breeding success. In a study in New York S0tate, however, adults breeding at PCB-contaminated sites along the Hudson River abandoned their eggs more commonly, and also hatched fewer eggs, than did populations of the species breeding at other New York sites. Tree Swallows may also be affected by acid rain, as they produce comparatively fewer and smaller fledglings in acidic wetlands, perhaps as a result of fewer sources of calcium. In another example, post-mortem analyses revealed that the bodies of Barn Swallows nesting along a highway in Maryland, USA, contained higher concentrations of lead than did those of their rural counterparts, although their breeding success did not appear to suffer.

A more important effect of environmental biocides is likely to be the decline in insect abundance, and the consequent loss of food, where insects are eliminated by pesticides or their foodplants destroyed by herbicides. In a recent study in Scotland, T. Benton and his colleagues found that, over a 27-year period, the numbers of arthropods caught in a suction trap were related to agricultural practices such as the use of pesticides; the more intense the farming, the fewer the arthropods. In turn, farmland bird numbers were low when farming was intense and their prey scarce. In contrast, the control of air pollution during the twentieth century, leading to an improvement in air quality, has probably led to an increase in the supply of insects in some areas, thus allowing hirundines to spread. In Britain, for example, Northern House Martins returned to breed in Inner London following the implementation of the Clean Air Act of 1956.

A number of measures can be taken to improve a species' breeding success and increase its numbers, at least locally. These include the controlling of House Sparrow numbers, the removal of old nests that contain ectoparasites in order to prevent the build-up of these, and the provision of artificial nests or nest-sites. To most people, the erection of nestboxes is probably the most familiar method. Those species that build mud nests are perhaps the least suited to using a box, although artificial nests for Barn Swallows and, in particular, Northern House Martins have had some success, and are available commercially, while boards erected at strategic sites can also provide a suitable starting point for a Barn Swallow's nest. In some areas Cliff Swallows readily use plaster nests, and burrowing species, such as the Collared Sand Martin, will nest at specially constructed sites containing pipes or other artificial tunnels. Species that use tree holes or other cavities for breeding often readily accept nestboxes, but usually in rural contexts. The Purple Martin is a notable exception, being a regular user of boxes in urban gardens, as well as in the countryside (see Relationship with Man).

Habitat change resulting from human activities is a mixed blessing for hirundines. Logging and forest clearance have removed many potential natural sites for cavity-nesters, but species that have adapted to using artificial sites have benefited from the expansion of cultivation and human settlements, roads and railways, sometimes spectacularly so. Barn and Cliff Swallow populations, for example, were probably small, and restricted to areas with cliffs and caves, before these species began to nest on buildings and bridges; they have expanded their ranges as a result of their association with humans. Conversely, the intensive farming methods employed on many modern farms can be detrimental to hirundines; not only are insects frequently eliminated by pesticides, but hedges and trees are often removed, and with them the good feeding sites that tend to surround them.

Some species, or local populations, rely almost entirely on artificial sites for nesting, and modern reports of, for instance, Barn Swallows, Northern House Martins or eastern Purple Martins using natural nest-sites are scarce. Other members of the family use both natural and artificial sites, as and when they are available. The appearance of new sites, such as newly constructed bridges, can increase local population sizes and ranges, as has been noted with, for example, the Wire-tailed and Rufous-chested Swallows in Africa. Range expansions of several species have been particularly noticeable over the last century or so, especially in North America, where the Barn, Cliff and Cave Swallows now have much wider breeding distributions than they once did. Some hirundines, however, such as the Black-and-rufous Swallow in the Afrotropics, have benefited little or not at all from the advent of artificial nest-sites. This is either because such sites are scarce or because the birds have not yet changed their innate nesting habits.

A consequence of the exploitation of artificial nest-sites is that species which formerly occurred in different places can now be found nesting side by side. This is the case, for example, with Barn Swallows and Cave Swallows in south-west USA, where the latter species is spreading north. This may lead to competition for local resources and even to the two swallows hybridizing, possibly by males of one species forcing extra-pair copulations on females of the other (see Breeding).

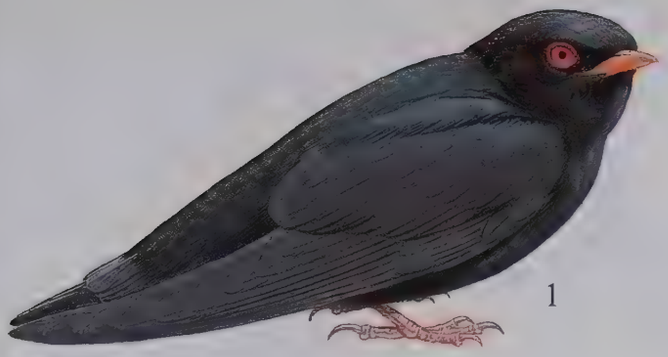

PLATE 62

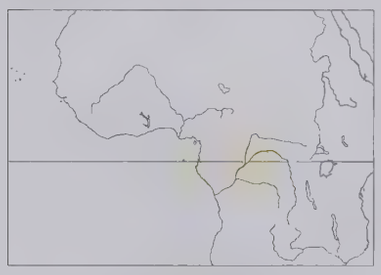
inches 3
cm 8



Subfamily PSEUDOCHELIDONINAE
Genus *PSEUDOCHELIDON* Hartlaub, 1861

1. African River Martin
Pseudochelidon eurystomina

French: Pseudolangrayen d'Afrique **Spanish**: Avión Ribereño Africano
German: Rotaugenschwalbe

Taxonomy. *Pseudochelidon eurystomina* Hartlaub, 1861, Gabon.
Monotypic.
Distribution. W Gabon (Gamba, Animba and near Libreville) and PRCongo (Conkouati Reserve), and DRCongo (upper and middle R Congo, lower R Ubangi).

Descriptive notes. 14 cm. Plumage is mostly blue-black or purple-black, with green sheen on back; tail black and square, central pair of feathers slightly pointed; sooty-brown underwing-coverts; bill large, orange-red; eye red, pink eyering; feet brownish-pink. Sexes alike. Juvenile is dull sooty-brown, greyer below. Voice. Song is a jingling noise given during displays; flight call described as "kee-r-r" or "chee-chee-chee" and "chattering" call recorded in resting flock.
Habitat. Forested rivers, coastal savanna. Feeds high over forest and along rivers. Roosts in reedbeds or in vegetation along rivers; also recorded roosting on buildings.
Food and Feeding. Mainly flying ants (Hymenoptera) recorded in analyses of stomach contents; also takes lycaenid butterflies, moths and other small Lepidoptera, flies (Diptera), beetles (Coleoptera), various hymenopterans, bugs (Hemiptera) and termites (Isoptera). In faeces and pellets collected in a breeding colony in Gabon, 65% of items were winged ants and 24% were termites. Usually seen in flocks. Flight rapid, with some gliding.
Breeding. Eggs and nestlings in Feb-Mar in DRCongo; breeding activities in Sept-Nov in Gabon and PRCongo. Colonial, colony sizes c. 800 birds on R Congo, 20-600 birds in Gabon, in one case using same site as Rosy Bee-eater (*Merops malimbicus*); at a Gabon colony, 2-3 pairs/m^2 and up to 9 holes/m^2, although probably not all holes in use. Nest in hole in sandbar in river (DRCongo), in grassy sand ridge near coast, or on gently inclined surface on coastal plain (Gabon), digs own burrow, but may also use existing bee-eater burrow; four burrows in Gabon 130-179 cm long (average 152 cm), nest-cavity 50-80 cm (average 66 cm) below surface; nest made of leaves, twigs, copal tree seed pods (DRCongo), or grass (Gabon). Clutch 3 eggs; no information on incubation and brood-rearing periods.
Movements. Migrates between the two breeding areas. Present in DRCongo mid-Dec/Jan to Apr/May; main passage across Gabon in Jun to early Sept, although begins as early as Apr, returning from late Oct to Nov but mainly Dec-Mar. Present in Gabon (Gamba) from mid-Aug, and on coast of PRCongo from mid-Sept. Not known if same birds breed at both sites or spend non-breeding season at one of them.
Status and Conservation. Not globally threatened. Data-deficient. Breeding area possibly more extensive than originally thought; only recently discovered near Libreville (Gabon) and in Conkouati Reserve (PRCongo); other stretches of coastal Gabon may also hold colonies. Occurs in large numbers on breeding grounds, also on migration in Gabon, e.g. a flock of c. 15,000 seen in 1997; smaller numbers seen on passage in N PRCongo, and in 1994 3-4 also observed in Central African Republic. In DRCongo, large numbers of adults and nestlings taken for food by local people; this hunting pressure possibly increasing. Breeding colonies vulnerable to flooding; on R Congo nesting sites exposed only in Feb-Mar and Jul-Aug.
Bibliography. Alexander-Marrack (1994), Bannerman (1939, 1953), Borrow & Demey (2001), Brosset & Érard (1977, 1986), Chapin (1953, 1954), Christy & Clarke (1994), Dean (2000), Dowsett (1989), Dowsett & Dowsett-Lemaire (1991, 1993, 1997), Dowsett & Forbes-Watson (1993), Dowsett *et al.* (1999), Érard (1981), Fishpool & Evans (2001), Fry (1992), Keith *et al.* (1992), Lippens & Wille (1976), Mackworth-Praed & Grant (1973), Maisels & Cruickshank (2000), Pedersen (2000), Schouteden (1922), Sinclair (1998, 2003), Stattersfield & Capper (2000).

2. White-eyed River Martin
Pseudochelidon sirintarae

French: Pseudolangrayen d'Asie **Spanish**: Avión Ribereño Asiático
German: Weißaugenschwalbe

Taxonomy. *Pseudochelidon sirintarae* Thonglongya, 1968, Bung Boraphet (or its immediate vicinity), central Thailand.
Sometimes placed in monotypic genus *Eurochelidon* on basis of differences from *P. eurystomina* in bill size, eye size and colour and foot size, and of toe proportions, but these considered relatively minor. Monotypic.
Distribution. Breeding range unknown, possibly along rivers in Myanmar, S China, N or C Thailand or Laos; C Thailand in non-breeding season.

Descriptive notes. 15 cm. Plumage is mostly black with green sheen; rump silvery white, wings black; tail black with green gloss, central feathers greatly elongated; underwing-coverts light brown; bill broad, greenish-yellow; eye, including margin of lid, white; feet flesh-coloured. Sexes alike. Juvenile is duller, without elongated tail feathers. Voice. Nothing recorded.
Habitat. Recorded as roosting with other hirundinids in reedbeds. May breed along forested rivers, as *P. eurystomina*.
Food and Feeding. Unknown. One specimen had a large beetle in its stomach. Flight reported as buoyant.
Breeding. Unknown. If breeding on rivers in Thailand, season probably Mar-Apr, when water levels low, but immatures collected late Jan to early Feb suggest earlier breeding. May nest in holes in river sandbars, as *P. eurystomina*, but it has also been suggested, on basis of foot structure and large eyes, that it may not burrow and may be partially crepuscular or nocturnal, and possibly associated with caves.
Movements. Known only as non-breeding visitor in Nov-Feb to Bung Boraphet, in C Thailand.
Status and Conservation. CRITICAL. CITES I. Possibly extinct. First discovered in 1968, near L Bung Boraphet, where over 100 said to have been caught in following few years, but has apparently declined since then. Has not been seen for over 20 years. Twelve collected from roosts and six seen at Bung Boraphet in 1978; there are also rumours of this species being sold in local markets, as well as unconfirmed sightings, but none since 1986. No evidence of the species was found in surveys of rivers in N Thailand in 1969 and N Laos in 1996, nor in searches around Bung Boraphet in 1979-1981 and 1988. Trapping for food and destruction of the roost-site (by burning to clear area for lotus cultivation) have greatly reduced numbers of hirundinids roosting there. Specimens possibly also taken for zoos or other collections. Threats to potential breeding sites may come from the adverse impact on rivers of dams, deforestation and intensification of agriculture, as well as disturbance by fishermen, hunters and sand-dredging. L Bung Boraphet is now designated a Non-hunting Area, although trapping has continued. The priority conservation measure is to locate the breeding areas.

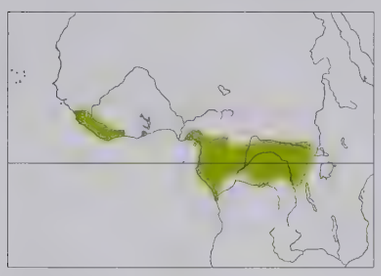
PLATE 63

inches 3

cm 8

Subfamily HIRUNDININAE



Genus *PSALIDOPROCNE* Cabanis, 1850

3. Square-tailed Saw-wing

Psalidoprocne nitens

French: Hirondelle à queue courte **Spanish**: Golondrina Colicuadrada
German: Grünglanzschwalbe
Other common names: (Square-tailed) Roughwing Swallow

Taxonomy. *Atticora nitens* Cassin, 1857, River Muni, Gabon.
Two subspecies recognized.
Subspecies and Distribution.
P. n. nitens (Cassin, 1857) - S Guinea, Sierra Leone, Liberia, S Ivory Coast, S Ghana, and from SE Nigeria E to N & C DRCongo and S to Gabon, PRCongo and extreme NW Angola (Cabinda).
P. n. centralis Neumann, 1904 - NE DRCongo.

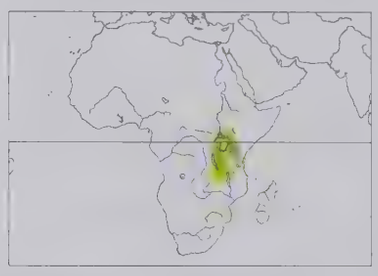
Descriptive notes. 11 cm; 10 g. Plumage is mostly dark brown with green gloss; wings and square-ended tail blackish-brown; chin and throat grey-brown; underwing-coverts blackish-brown with slight gloss. Differs from congeners and from *Petrochelidon fuliginosa* in having square-tipped, not forked, tail. Sexes alike. Juvenile is duller brown. Race *centralis* has blackish-brown throat with green sheen. Voice. Not very vocal; twitters in flocks and has a quiet "sip" call.
Habitat. Lowland primary and secondary forest. Feeds within forest clearings or above canopy; also around villages and cultivated ground.
Food and Feeding. Diet includes beetles (Coleoptera), flies (Diptera), flying ants (Hymenoptera), termites (Isoptera). Forages in pairs or in small flocks of up to 40 individuals, sometimes with *P. obscura* and *Hirundo leucosoma*; both high over forest and low over ground. Flight weak and fluttering.
Breeding. End of dry season and start of rains: Oct-May in Liberia, Jan-Jul in Cameroon, Jul-Mar in Gabon, Aug in Cabinda, and Feb, May and Jul-Oct in DRCongo. Solitary. Digs burrow 0·3-2 m long in vertical bank (including mine shafts and road cuttings), terminal nest-chamber lined with lichens and moss. Clutch 2 eggs (one clutch of 4 possibly result of two females laying in same nest); no information on incubation and fledging periods.
Movements. Sedentary, but some post-breeding movement occurs, e.g. in Liberia and C Ivory Coast.
Status and Conservation. Not globally threatened. Generally localized and uncommon to rare; considered to be common in Liberia, and locally common in Gabon, Ghana and NE DRCongo. Appears to make less use of artificial sites than does *P. pristoptera*. May receive some benefit in short term from forest destruction, because logging roads and newly burnt farmland provide new potential nest-sites, but would suffer loss of habitat in long term. Has decreased in Ivory Coast and Ghana.
Bibliography. Allport *et al.* (1989), Ash & Sharland (1986), Bannerman (1953), Borrow & Demey (2001), Brosset & Érard (1986), Chapin (1953), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dean (1974, 2000), Dowsett (1989), Dowsett & Dowsett-Lemaire (1991, 1993, 1997), Dowsett & Forbes-Watson (1993), Dutson & Branscombe (1990), Elgood *et al.* (1994), Fishpool & Evans (2001), Gartshore (1989), Gartshore *et al.* (1995), Gatter (1988, 1997), Grimes (1987), Keith *et al.* (1992), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1973), Pedersen (2000), Thiollay (1985).

4. Mountain Saw-wing

Psalidoprocne fuliginosa

French: Hirondelle brune **German**: Kamerunschwalbe **Spanish**: Golondrina Camerunesa
Other common names: Cameroon (Mountain) Saw-wing, Mountain Roughwing (Swallow)

Taxonomy. *Psalidoprocne fuliginosa* Shelley, 1887, Mount Cameroon.
Forms a superspecies with *P. albiceps*. Birds from Bioko described as race *poensis*, but considered indistinguishable. Monotypic.
Distribution. W Cameroon (Mt Cameroon) and Bioko (Fernando Póo).



Descriptive notes. 12 cm; 11-14 g. Has dull chocolate-brown plumage, with wings darker brown; tail moderately forked; underwing-coverts smoky brown. Differs from *P. obscura* in having browner and duller plumage, and from *P. pristoptera* (race *petiti*) in darker underwing; distinguished from both by less deeply forked tail. Sexes alike. Juvenile is paler brown. Voice. Quiet, melodious song "dju-dju-diob-djuob-djuob"; calls in flight "see-su", "tchik-tchuk".
Habitat. Forest, forest edge and clearings, montane grassland, plantations, farmland, around human habitations. Present from sea-level up to 3000 m on S & SE slopes, and at 600-2900 m on N slope, of Mt Cameroon; found above 300 m on Bioko.
Food and Feeding. Diet not known. Generally forages in pairs or in small groups, though one flock of over 50 individuals recorded; sometimes with other swallows and swifts (Apodidae). Flight leisurely, with frequent swoops and glides; sometimes pauses before swooping down; will fly low over ground.
Breeding. Oct-Mar. Usually solitary, but group of 10-15 pairs also recorded and 4-5 pairs inspecting a nest-site. Nest a tightly woven pad of lichens and moss, placed on ledge or in hole in cliff, ravine or cave; one group nested in a cave beside a waterfall, and one pair used the brickwork of an outhouse. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Probably resident; some records suggest possible post-breeding movements.
Status and Conservation. Not globally threatened. Restricted-range species: present in Cameroon Mountains EBA. Common, and occurring in a variety of habitats, within its small range. Also recorded on Obudu Plateau and Mambilla Plateau, in E Nigeria, but status there not known.
Bibliography. Amadon (1953), Ash *et al.* (1989), Bannerman (1953), Basilio (1963), Borrow & Demey (2001), Collar & Stuart (1985), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Eisentraut (1956, 1963), Elgood *et al.* (1994), Fishpool & Evans (2001), Keith *et al.* (1992), Louette (1981), Mackworth-Praed & Grant (1973), Mills & Cohen (2004), Pérez del Val (1996), Serle (1965, 1981), Stuart (1986), Wells (1968), Young (1946).

5. White-headed Saw-wing

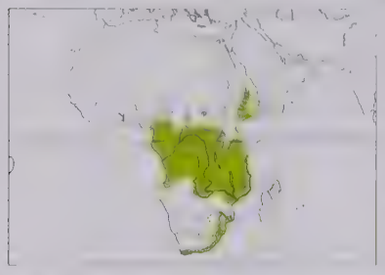
Psalidoprocne albiceps

French: Hirondelle à tête blanche **Spanish**: Golondrina Cabeciblanca
German: Weißkopfschwalbe
Other common names: White-headed Roughwing

Taxonomy. *Psalidoprocne albiceps* P. L. Sclater, 1864, Uzinza, Tabora District, Tanzania.
Forms a superspecies with *P. fuliginosa*. Two subspecies recognized.
Subspecies and Distribution.
P. a. albiceps P. L. Sclater, 1864 - extreme SE Sudan and E DRCongo, Uganda and W Kenya S to Tanzania (mainly around L Victoria and in W), N Zambia and N Malawi.
P. a. suffusa Ripley, 1960 - N Angola (Lunda Sul).

Descriptive notes. 13 cm; 11-14 g. Male has distinctive white crown, forehead, side of head, chin and throat, black bar from bill through eye and ear-coverts; rest of plumage brownish-black with slight green sheen; tail moderately forked; underwing-coverts grey-brown. Female is similar to male, but with variable amount of white on crown (usually only few white feathers), throat less pure white, tail shorter. Juvenile lacks white on head, has throat ashy brown, tail shorter. Race *suffusa* differs from nominate in having less white on crown, greyer ear-coverts, throat and underwing. Voice. Not very vocal; has twittering call.
Habitat. Savanna, woodland, scrub and forest in upland areas, including miombo woodland and montane, evergreen and riparian forest, to c. 2400 m. Feeds mainly in clearings, at forest edges, and over bush and cultivation.
Food and Feeding. Two stomachs contained flying ants (Hymenoptera); beetles (Coleoptera) and flies (Diptera) also recorded in diet. Feeds in small groups, usually of 2-4 individuals, but occasionally up to 40. Flight slow and fluttery, low over ground or vegetation.
Breeding. Aug-Sept in Sudan, Nov-Mar in Kenya, Apr-Jun in Uganda, Apr-Mar and Nov in Rwanda, May-Oct in DRCongo, Dec-Jan in Zambia and Feb in Malawi; may be double-brooded. Solitary or in small groups. Digs burrow 25-60 cm long in bank, such as road cutting, or may adapt old rodent burrow; terminal chamber with nest made of grass, lichens and feathers. Clutch 2-4 eggs; incubation and fledging periods not documented.
Movements. Migratory in S of range. Breeding birds present in NE Zambia from Oct to early May, and in Malawi during Oct-Apr. Vagrants recorded in Ethiopia, S & C DRCongo, W & S Zambia and Zimbabwe.
Status and Conservation. Not globally threatened. Generally common in much of range; only locally common in DRCongo. Isolated Angolan race *suffusa* uncommon and very local, found only near Cacolo, in SE Lunda Sul.
Bibliography. Aspinwall & Beel (1998), Benson (1951, 1953), Benson & Benson (1977), Benson & Pitman (1957), Benson *et al.* (1971), Britton (1980), Brown & Britton (1980), Byaruhanga *et al.* (2001), Cave & Macdonald (1955), Chapin (1953), Dean (2000), Dowsett (1990), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Friedmann & Williams (1969), Horner (1999), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1960, 1963, 1973), Nikolaus (1987), Pedersen (2000), Penry (1979), Short *et al.* (1990), van Someren (1916), van Someren & van Someren (1949), Stevenson & Fanshawe (2002), Waiyaki (1998), Zimmerman (1972), Zimmerman *et al.* (1996).

6. Black Saw-wing



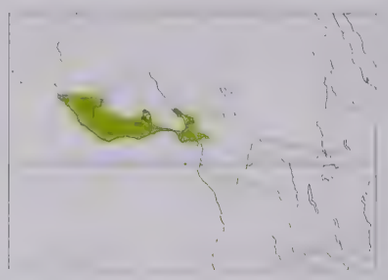
Psalidoprocne pristoptera

French: Hirondelle hérissée **German**: Erzschwalbe **Spanish**: Golondrina Negra
Other common names: Black Roughwing; Blanford's Saw-wing (*blanfordi*); Blue/Fork-tailed Saw-wing (*pristoptera*); Brown Saw-wing/Roughwing (*antinorii*); Congo/Mangbettu Saw-wing (*mangbettorum*); Eastern Saw-wing (*orientalis*); Ethiopian/Kaffa Saw-wing (*oleaginea*); Petit's Saw-wing/Roughwing (*petiti*); Shari/Western Saw-wing (*chalybea*)

Taxonomy. *Hirundo* (*Chelidon*) *pristoptera* Rüppell, 1836, Simen Province, Ethiopia.
Forms a superspecies with *P. obscura*. Taxonomy complex, and some races overlap in range with apparently little interbreeding; hence, races *petiti*, *chalybea*, *blanfordi*, *antinorii*, *oleaginea*, *mangbettorum*, *orientalis* and *holomelas* often treated as full species; further work required in order to assess relationships within the group. Additional proposed races include *kosteri* (Benguela, in W Angola), *percivali* (Malawi, Zimbabwe and Mozambique) and *bamingui* (R Bamingui, in Central African Republic), but these are not clearly distinguishable. Twelve subspecies currently recognized.

On following pages: 7. Fanti Saw-wing (*Psalidoprocne obscura*); 8. Grey-rumped Swallow (*Pseudhirundo griseopyga*); 9. White-backed Swallow (*Cheramoeca leucosterna*); 10. Mascarene Martin (*Phedina borbonica*); 11. Brazza's Martin (*Phedina brazzae*).

Subspecies and Distribution.
P. p. petiti Sharpe & Bouvier, 1876 - E Nigeria, S Cameroon, Gabon and extreme NW Angola (Cabinda).
P. p. chalybea Reichenow, 1892 - N & C Cameroon E to Central African Republic, W Sudan and N & C DRCongo.
P. p. pristoptera (Rüppell, 1836) - W Highlands of N Ethiopia.
P. p. blanfordi Blundell & Lovat, 1899 - Highlands of WC Ethiopia.
P. p. antinorii Salvadori, 1884 - C & S Ethiopia.
P. p. oleaginea Neumann, 1904 - SW Ethiopia and SE Sudan.
P. p. manghettorum Chapin, 1923 - S Sudan S to NE DRCongo.
P. p. ruwenzori Chapin, 1932 - E DRCongo.
P. p. reichenowi Neumann, 1904 - Angola, S DRCongo and Zambia.
P. p. massaica Neumann, 1904 - Kenya and N & C Tanzania.
P. p. orientalis Reichenow, 1889 - S Tanzania and E Zambia S to E Zimbabwe and C Mozambique.
P. p. holomelas (Sundevall, 1850) - S Zimbabwe and S Mozambique S to E & S South Africa.



Descriptive notes. 13 cm; 12 g. Dark body and forked tail distinctive. Nominate race is black with purple-blue sheen; wings blackish-brown; tail blackish-brown with green gloss, strongly forked, outer feathers broad; underwing-coverts white. Sexes similar, but female with shorter tail than male. Juvenile is duller, dark brown. Races differ in size, tail shape and tail-fork depth, wing length, colour of sheen and colour of underwing-coverts: *blanfordi* resembles nominate, but with gloss blue-green; *antinorii* has gloss more purple in colour; *oleaginea* has an oily green gloss, with outer rectrices narrower than nominate; *petiti* is brownish-black with slight bronzy gloss, white underwings tinged grey; *chalybea* has oily green gloss, deeply forked tail, grey underwing-coverts; *manghettorum* differs from previous in having underwing-coverts white; *ruwenzori* has dull green gloss and grey-brown underwing-coverts; *holomelas* resembles last, but has longer tail; *massaica* differs from previous in longer wings; *reichenowi* has dull green gloss and greyish-white underwing-coverts; *orientalis* also has dull green gloss, but white underwing-coverts and a more deeply forked tail. Voice. Not very vocal; calls include high-pitched "see-see", described as "chirr-chirr-cheeeu" for *holomelas* and "tseeu-tseeu-tsee-ip" for *orientalis*; also a "chirp" alarm and "hui" during courtship.
Habitat. Savanna, woodland, bush, forest, river valleys, villages and plantations, also montane grassland and moorland. Usually near water. Wide altitudinal range, e.g. *oleaginea* 300-2400 m, but Ethiopian races mainly above 1200 m. Feeds mainly in clearings and forest edges, or over water.
Food and Feeding. Diet includes beetles (Coleoptera), flies (Diptera), and hymenopterans such as ants and ichneumonids. Forages alone, in pairs or in small groups of 6-15 individuals, often low over ground; average height 7 m. Flight weak and fluttering, often changing height, flying up to canopy and then swooping down. Most active at dawn and dusk.
Breeding. Usually in local wet season, i.e. Apr-Jun and Oct-Nov in Cameroon, Apr-Jul in Gabon, Feb-Sept in DRCongo, Feb-Jul in Ethiopia, Jan-Mar and Jun-Dec in Tanzania, Mar in Angola, Jan-Mar in Zambia, Feb-Mar, Aug and Dec in Malawi, Oct-Mar and May in Mozambique, Jul-Apr in Zimbabwe, and mainly Aug-Mar in South Africa; may be double-brooded. Often solitary, but group of ten pairs recorded. Nest-burrow 30-60 cm long, usually c. 45 cm, dug by both sexes, taking up to 3 weeks, in vertical bank, sandy cliff, quarry or road cutting, terminal chamber filled with dry grass and lichen; pre-existing holes also used, and in South Africa (race *holomelas*) recent record of several pairs nesting in drainage pipes of concrete bridge. Clutch 1-3 eggs, usually 2; incubation probably by female alone, at five nests 6-20% of incubation bouts less than 8 minutes, 28-62% more than 15 minutes (up to 50 minutes); incubation period c. 19 days; chicks fed by both sexes, at intervals of mostly 4-20 minutes, nestlings come to burrow entrance to be fed a few days before fledging, fledge at 24-27 days.
Movements. Not well understood. Mainly resident in Gabon, Sudan, Ethiopia and E Africa, making some local post-breeding movements e.g. to lower altitudes. Partial migrant in some areas, e.g. Malawi, Zambia, Mozambique; in South Africa and Zimbabwe breeders present mainly Aug-Apr, perhaps in part migrating to Mozambique, where increased numbers in non-breeding season; some remain all year in S, especially on KwaZulu-Natal coast. Possibly migratory in Angola (although may be resident in Cabinda) and S DRCongo, leaving in dry season. Vagrant in Botswana.
Status and Conservation. Not globally threatened. Generally common to locally abundant, especially in highlands; not common in lower Congo Basin, W Sudan, E African plains, S Zambia and C Zimbabwe. Does not utilize artificial nest-sites to great extent, and may be affected by loss of natural habitat, although does use forestry road cuttings.
Bibliography. 7. Fanti Saw-wing
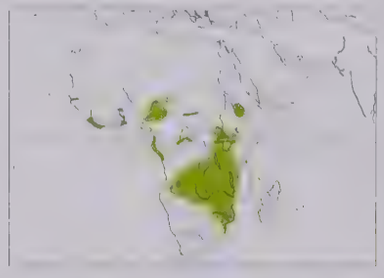
Psalidoprocne obscura

French: Hirondelle fanti **German**: Scherenschwanzschwalbe **Spanish**: Golondrina Fanti
Other common names: Fanti/Fantee Roughwing

Taxonomy. *Hirundo obscura* Hartlaub, 1855, Dabocrom, Ghana.
Forms a superspecies with *P. pristoptera*. Monotypic.
Distribution. S Senegambia E to C & S Nigeria and W Cameroon.
Descriptive notes. 17 cm; 9-10 g. Has glossy dark green plumage; wings and tail black with green gloss, tail long and strongly forked; underwing-coverts dull brown. Distinguished from *P. pristoptera* by longer tail, dark glossy green plumage and brown underwing-coverts. Sexes similar, female



with shorter tail than male. Juvenile is duller brown, with shorter tail. Voice. Not very vocal; call is a quiet "seep".
Habitat. Woodland, forest edge, grassland and rivers; usually near water. Feeds in clearings or forest edge and over grassland.
Food and Feeding. Diet includes beetles (Coleoptera). Forages in pairs or small groups, sometimes up to 50 together, often low over grassland or water, or around trees. Flight slow and buoyant. Also hawks insects from perch in tree.
Breeding. In rainy season, generally May-Aug; Sept-Oct in Sierra Leone and May-Oct in Nigeria. Solitary or in small groups. Both sexes dig burrow c. 60 cm long in riverbank or other vertical bank, road cutting or mine shaft, nest-chamber lined with plant fibres and moss. Clutch 2 eggs; incubation and fledging periods not documented.
Movements. Resident in some areas, e.g. S Nigeria, but breeding visitor farther N. Generally more common in dry season in S of range, and in wet season in N; commonest in Gambia in Jul-Nov; in Ivory Coast, most common Oct-May in S and Apr-Sept in N; in Ghana, most numerous Sept-Mar in S and Jun-Sept in N. Vagrants recorded in SW Niger, SE Burkina Faso and Central African Republic.
Status and Conservation. Not globally threatened. Uncommon to locally common; locally common in, for example, Sierra Leone, Ivory Coast and Nigeria. Rare to not uncommon in Liberia.
Bibliography. Bannerman (1953), Bates (1930), Borrow & Demey (2001), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood, Fry & Dowsett (1973), Elgood, Heigham *et al.* (1994), Field (1974), Fishpool & Evans (2001), Fry (1980), Gatter (1988, 1997), Gore (1990), Grimes (1987), Jensen & Kirkeby (1980), Keith *et al.* (1992), Louette (1981), Mackworth-Praed & Grant (1973), Marchant (1942), Morel & Morel (1990), Serle (1949), Thiollay (1985), Wilkinson & Beecroft (1988).

Genus *PSEUDHIRUNDO* Roberts, 1922

8. Grey-rumped Swallow
Pseudhirundo griseopyga

French: Hirondelle à croupion gris **German**: Graubürzelschwalbe **Spanish**: Golondrina Culigrís
Other common names: Andrew's/Kenya Swallow ("*andrewi*")

Taxonomy. *Hirundo griseopyga* Sundevall, 1850, Natal, South Africa.
Once included in genus *Hirundo* because of its coloration, but DNA data indicate close relationship to other members of the "core martin group". Proposed races *liberiae* (from Liberia) and *gertrudis* (from NE Nigeria and N Cameroon) undiagnosable. "*Hirundo andrewi*", based on single specimen caught at L Naivasha, Kenya, in 1965, has been treated as a race of present species but now generally thought to be an aberrant, darker individual (grey-brown below, darker chest side) of nominate race, probably on migration from unknown breeding area (possibly Ethiopia). Two subspecies normally recognized.
Subspecies and Distribution.
P. g. melbina (J. Verreaux & E. Verreaux, 1851) - Gambia, E Sierra Leone, Liberia, SW Ivory Coast, Ghana, and coast from Equatorial Guinea S to extreme NW Angola (Cabinda).
P. g. griseopyga (Sundevall, 1850) - E Nigeria, N Cameroon, N Central African Republic, extreme S & E Sudan, Ethiopia, E PRCongo, and from W & E DRCongo, Uganda and W Kenya S to Angola, extreme N Namibia, N Botswana, NE South Africa (S to KwaZulu-Natal) and N & E Swaziland.

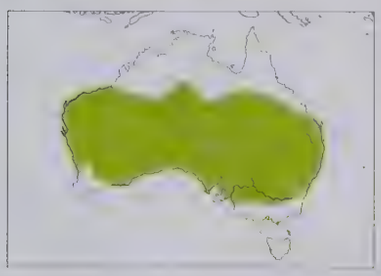
Descriptive notes. 14 cm; 8-12 g. Crown and ear-coverts to hindneck are dark brown; back and wings glossy dark blue, rump and upper-tail-coverts grey-brown; tail strongly forked, dark brown with blue gloss; underparts all white, pinkish wash from chin to breast in fresh plumage. Distinguished from other hirundinids by combination of deeply forked tail without white spots and grey rump. Sexes alike. Juvenile is browner with pale feather fringes above, abdomen and flanks grey, rest of underparts white with buff-pink wash, greyer near breast and side of neck, tail shorter. Race *melbina* has darker brown rump than nominate. Voice. Not very vocal; song is a weak twittering; also a grating "chraa" in flight.
Habitat. Open areas such as floodplains, grassland, savanna or open woodland, often near water. In both lowland and upland areas, to c. 2200 m in E Africa and 2300 m in Malawi. Often feeds over burnt and cleared ground; roosts in reeds, also recorded as roosting on bare ground.
Food and Feeding. Diet includes beetles (Coleoptera) and flies (Diptera). Forages mainly low over water, also over open ground and around tree canopies, at average height of 8 m, often with other hirundines. Flight weak and erratic. Sometimes lands to eat insect caught in flight. Follows tractors to feed on flushed insects.
Breeding. Mainly in dry season, also sometimes breeding opportunistically to take advantage of good conditions: Nov-May in W Africa, Mar-Apr and Dec in Ethiopia, May, Jul-Oct and Mar (peak Aug-Sept) in E Africa, Aug-Sept in Angola, Jul-Sept in Zambia and Mozambique, Jul-Nov (peak Jul-Aug) in Zimbabwe, and May-Dec (peak Jun-Aug) in South Africa. Solitary or in small groups of 3-10 pairs; sometimes near *Riparia congica* in DRCongo. Digs burrow up to c. 1 m long at steep angle into ground in open situation, e.g. sandbar, dune, ploughed field, golf course, various kinds of sports field, or airfield, also recorded in grass-covered, gently sloping riverbank; rodent holes, old kingfisher (Alcedinidae) or bee-eater (*Merops*) burrows and holes in termite (Isoptera) mounds also used; nest-chamber lined with grass. Clutch 1-5 eggs (2-3 near equator); incubation and fledging periods not documented. Nests often flooded if rain falls.
Movements. Not well understood. Forms large non-breeding flocks, usually up to c. 200 individuals, sometimes to 3000; often moves away from breeding sites in rainy season. Resident on

R Congo and in Ethiopia. Movements not clear in W & C Africa, but local shifts in some areas; occurs Nov-Feb in Gambia, and is a partial migrant in Liberia; sporadic in Nigeria. Numbers vary seasonally in E Africa. Usually present Apr-Oct in Zimbabwe, but resident in dry years. Recorded mainly Apr-Oct in Botswana, Apr-Sept in E South Africa and Mar-Sept in Zambia; those populations possibly spend non-breeding season in Mozambique. Several records outside main range, e.g. Mali, N Ivory Coast, Burkina Faso, Benin, N DRCongo; even three in S Atlantic off Angola.

Status and Conservation. Not globally threatened. Scarce to uncommon in some areas, locally common or abundant in others. Generally scarce in W Africa, but locally not uncommon in Liberia; rare in Sudan, locally abundant in Ethiopia; uncommon in E Africa; common on R Congo and in DRCongo, Zambia and Malawi; locally common in Botswana (in N), Zimbabwe (Mashonaland Plateau) and E South Africa; formerly bred along coast of KwaZulu-Natal but now confined to NE. Fairly adaptable; does not use artificial nests, but sometimes nests on fields and other sites associated with human settlements.

Bibliography. Aspinwall (1980a), Bannerman (1953), Benson (1951, 1980), Benson & Benson (1977), Benson *et al.* (1971), Borrow & Demey (2001), Brooke (1984a), Byaruhanga *et al.* (2001), Clancey (1964b), Colston & Curry-Lindahl (1986), Dean (2000), Dowsett (1972a), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Earlé (1987b), Elgood, Fry & Dowsett (1973), Elgood, Heigham *et al.* (1994), Fry (1973), Gatter (1997), Gore (1990), Grimes (1987), Harrison *et al.* (1997), Irwin (1981), Jourdain & Shuel (1935), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lowe (1938), Macdonald (1984), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993a), Penry (1994), Schmidl (1982), Serle (1957), Short *et al.* (1990), Sinclair & Hockey (1996), Stevenson & Fanshawe (2002), Tarboton (2001), Taylor (1979a), Tree (1976), Urban & Brown (1971), Waugh (1978), Winterbottom (1939), Zimmerman *et al.* (1996).

Genus *CHERAMOECA* Cabanis, 1850



9. White-backed Swallow

Cheramoeca leucosterna

French: Hirondelle à dos blanc **Spanish**: Golondrina Dorsiblanca
German: Weißrückenschwalbe
Other common names: Black-and-white/White-breasted Swallow

Taxonomy. *Hirundo leucosternus* [*sic*] Gould, 1841, Naomi River, New South Wales, Australia. Closely related to *Pseudhirundo*. Proposed races *marngli* from R Fitzroy (N Western Australia) and *stonei* from Warialda (New South Wales) undiagnosable. Species name often erroneously spelled *leucosternum* or *leucosternus*, but, being latinized Greek adjective, must agree with feminine genus. Monotypic.

Distribution. W, C, S & E Australia.

Descriptive notes. 15 cm; 12-16 g. Pied coloration distinctive. Has forehead, outer crown, mantle, chin, throat, upper breast and underwing-coverts white; centre of crown and band across face and hindneck grey-brown, rest of upperparts and lower breast, abdomen and undertail-coverts black with slight blue gloss; wings and tail brownish-black, tail strongly forked. Sexes alike. Juvenile is duller and browner, white parts buffy, tail shorter. Voice. Song is a twittering; also a harsh "check" uttered in flight.

Habitat. Open country, usually near water, such as rivers with sandy banks.

Food and Feeding. Diet includes beetles (Coleoptera), mirid bugs (Hemiptera), nematoceran flies, Lepidoptera, hymenopterans (including ants and parasitic wasps) and spiders (Araneae). Feeds alone or in small groups, often high up; mixes with other swallows. Flight fluttery and erratic.

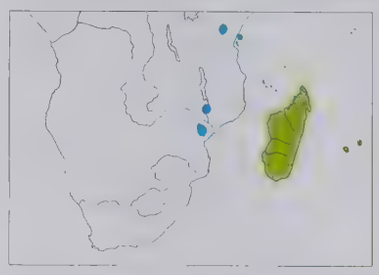
Breeding. Jul/Aug-Dec, after rains in arid regions; single-brooded. Solitary, or in groups of up to 80 pairs. Excavates own burrow in sandy cliff, riverbank, mine or quarry, but also uses burrow of other species e.g. bandicoot (Peramelidae) or rat kangaroo (Potoroinae), burrow c. 60 cm long, enlarged end chamber with nest made of dry grass and leaves. Clutch 4 or 5 eggs, occasionally 6; no information on incubation and fledging periods.

Movements. Generally resident; some post-breeding movements, e.g. deserts breeding sites in S Murray-Darling region. Occasional non-breeding visitor to N Western Australia (Kimberley and Rolling Downs regions). Forms small flocks after breeding.

Status and Conservation. Not globally threatened. Generally common, depending on presence of breeding sites. Has extended its range over the last century to coast of SE Queensland and New South Wales, W along the S coast, and S of R Swan. Uses artificial sites to only limited extent, but mining and quarrying operations have provided some nest-sites and this species probably benefits from land clearance.

Bibliography. Blakers *et al.* (1984), Campbell (1901), Congreve (1972), David & Gosselin (2002a), Edwards (1948), Lord (1956), Macdonald (1988), Morcombe (2000), Pizzey & Knight (1997), Saunders & Ingram (1995), Schodde & Mason (1999), Serventy (1970), Serventy & Whittell (1962), Simpson & Day (1998), Slater *et al.* (1989), Trounson & Trounson (1987), Waterman & Llewellyn (1968).

Genus *PHEDINA* Bonaparte, 1857



10. Mascarene Martin

Phedina borbonica

French: Hirondelle des Mascareignes **Spanish**: Golondrina de las Mascareñas
German: Maskarenenschwalbe
Other common names: Madagascar Martin

Taxonomy. *Hirundo borbonica* J. F. Gmelin, 1789, Bourbon = Mauritius.
Forms a superspecies with *P. brazzae*. Two subspecies recognized.

Subspecies and Distribution.
P. b. madagascariensis Hartlaub, 1860 - breeds Madagascar, possibly also Pemba I (off E Tanzania); migrates to E Africa.
P. b. borbonica (J. F. Gmelin, 1789) - Mauritius and Reunion I.

Descriptive notes. 15 cm; 18-24 g. Nominate race has crown and upperparts grey-brown with fine dark streaks; wings and tail dark brown, tail with shallow fork, tertials with pale edges when plumage fresh; underparts grey-brown, white on throat and abdomen, all with prominent streaks (broader than on upperparts); underwing-coverts grey-brown. Distinguished from *Riparia* species by streaked underparts. Sexes alike. Juvenile differs from adult in having broad white tips of secondaries. Race *madagascariensis* paler, with white undertail-coverts, and more pronounced streaking on breast. Voice. Song is a warbling "siri-liri siri-liri"; calls include a "chip" contact call; and copulatory and aggressive calls.

Habitat. Open and semi-open country. On Mauritius and Reunion, feeds over reservoirs, woodland and thickets, and along cliffs and the shore; to 1500 m on Mauritius, mainly at 200-500 m on Reunion. In Madagascar, over open ground, bush, woodland, forest, marshes and rice fields, from sea-level to 2400 m. In non-breeding season, also forages in areas of recently cleared forest and over canopy of *Brachystegia* woodland in Mozambique.

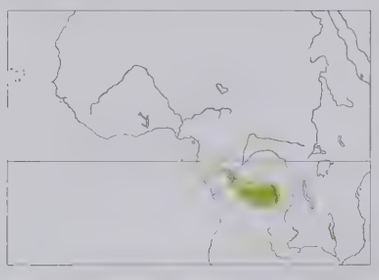
Food and Feeding. Diet includes beetles (Coleoptera) and Hymenoptera. Forages singly or in small groups with other swallows and swifts (Apodidae), close to ground and trees; flight slow and fluttering. Most active before dusk.

Breeding. Aug-Nov in Madagascar, Sept-Dec on Mauritius and Reunion. In groups of c. 3-20 pairs. Nest an open cup of twigs and other plant material such as dry grass, lined with finer material and feathers, placed in crevice or on ledge in rocks, in grass tuft, on roof, or in building, subterranean passage or cave, often 3-5 m above water. Clutch 2 eggs in Madagascar and on Mauritius, 2-3 on Reunion; incubation by female, period undocumented; both sexes feed brood, fledging period not known.

Movements. Resident with post-breeding dispersal on Mauritius and Reunion (nominate race); absent from breeding sites early Jan to mid-Aug. Race *madagascariensis* makes both local and long-distance movements after breeding; recorded in non-breeding season (mainly Jun-Aug) at widely scattered sites in E Africa, e.g. Kenya, Pemba I (off Tanzania), Malawi, C Mozambique (also one recent record S of R Save). Passage migrants recorded on Aldabra, Seychelles and other islands; vagrant on Amirante Is.

Status and Conservation. Not globally threatened. Common but somewhat local in Madagascar; no recent data on population size, but in mid-20th century large numbers ("hundreds") recorded in non-breeding season in Africa, e.g. in Malawi in Jun-Jul 1944 and Apr 1959 and in Mozambique in Jun-Jul 1968; much rarer in Africa in recent years. Status on Pemba I uncertain, recorded in non-breeding season but present also during breeding season. Nominate race fairly common, in 1973-1974 at least 70-75 pairs on Mauritius and possibly 200-400 pairs on Reunion; this race has been badly affected by cyclones, especially in 1861, after which few birds seen for several years, and to lesser extent in 1980.

Bibliography. Barré (1988), Barré & Barau (1982), Barré *et al.* (1996), Benson (1944), Berlioz (1946), Cheke (1987a, 1987b), Clancey *et al.* (1969), Cohen *et al.* (1997), Dee (1986), Delacour (1932), Diamond (1987), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Feare (1977), Horne (1987), Keith *et al.* (1992), Langrand (1995), Lewis & Pomeroy (1989), Maclean (1993a), Medland (1988), Milon *et al.* (1973), Morris & Hawkins (1998), Pakenham (1979), Rand (1936), Sheldon & Winkler (1993), Sinclair & Langrand (1998), Spottiswoode & Ryan (2002), Staub (1973), Yamagishi *et al.* (1997), Zimmerman (1978b), Zimmerman *et al.* (1996).



11. Brazza's Martin

Phedina brazzae

French: Hirondelle de Brazza **German**: Brazzaschwalbe **Spanish**: Golondrina del Congo
Other common names: Congo Martin, Brazza's Swallow

Taxonomy. *Phedina Brazzae* Oustalet, 1886, below Kwamouth, lower River Congo, DRCongo. Sometimes placed in a monotypic genus *Phedinopsis* and occasionally in *Riparia*. Is, however, close to *P. borbonica*, with which it forms a superspecies. Monotypic.

Distribution. S PRCongo, S DRCongo and NE Angola (N Lunda Norte).

Descriptive notes. 12 cm; 13 g. Plumage is dark brown above, darkest on head, with indistinct dark streaks from mantle to uppertail-coverts; wings and tail dark brown, tail square-ended; underparts white with thick dark streaks, breast sometimes with grey-brown wash; underwing-coverts dark brown. Differs from *Riparia* species in having striped underparts. Sexes alike. Juvenile has pale edges and rufous tips of upperpart feathers, greyish chin and throat, more diffuse stripes below. Voice. Unknown.

Habitat. Forested rivers.

Food and Feeding. Diet includes termites (Isoptera). Forages in flocks over rivers, sometimes with *Cecropis abyssinica*; flight slow and heavy.

Breeding. End of dry season, Jul-Oct. Small, loose groups. Nest in burrow c. 50 cm long in riverbank or ditch, nest-chamber lined with dry grass and feathers. One clutch of 3 eggs recorded; incubation and fledging periods not documented. Late nests may be subject to flooding.

Movements. No information; recorded E of 20° E only when breeding.

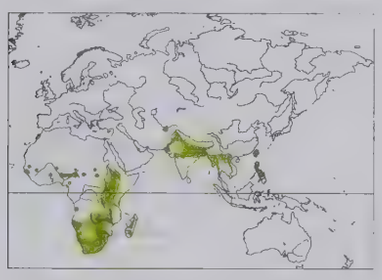
Status and Conservation. Not globally threatened. Data-deficient. Uncommon and local, with limited range. Probably subject to human predation.

Bibliography. Borrow & Demey (2001), Chapin (1953), Dean (2000), Dowsett (1989), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Keith *et al.* (1992), Lippens & Wille (1976), Lynes (1938), Mackworth-Praed & Grant (1973), Pedersen (2000), Rand *et al.* (1959), Sinclair & Ryan (2003), Stattersfield & Capper (2000).

PLATE 64

inches 3

cm 8



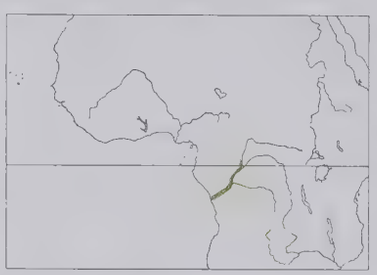
Genus *RIPARIA* T. Forster, 1817

12. Plain Martin

Riparia paludicola

French: Hirondelle paludicole **Spanish**: Avión Paludícola
German: Braunkehl-Uferschwalbe
Other common names: African/Brown-throated/Grey-breasted Sand Martin, Plain Sand Martin; Indian Sand Martin (*chinensis*)

Taxonomy. *Hirundo paludicola* Vieillot, 1817, South Africa.
Forms a superspecies with *R. congica*, *R. riparia* and *R. diluta*. Race *tantilla* sometimes included in *chinensis*. Name *paludibula* has priority over *minor*, but former has not been in use since at least 1894, and latter thus retained by virtually all recent authors. Nine subspecies recognized.
Subspecies and Distribution.
R. p. mauritanica (Meade-Waldo, 1901) - W Morocco.
R. p. minor (Cabanis, 1850) - locally from Senegambia E to Sudan and N Ethiopia.
R. p. schoensis Reichenow, 1920 - Ethiopian Highlands.
R. p. newtoni Bannerman, 1937 - SE Nigeria and adjacent W Cameroon.
R. p. ducis Reichenow, 1908 - E DRCongo, Uganda and W & C Kenya S to Burundi and N & C Tanzania.
R. p. paludicola (Vieillot, 1817) - W & SW Angola, Zambia, S Tanzania and Malawi S to South Africa.
R. p. cowani (Sharpe, 1882) - E Madagascar.
R. p. chinensis (J. E. Gray, 1830) - S Tadjikistan, N Afghanistan, Pakistan and N India E to Myanmar, S China (S Yunnan) and Indochina, also Taiwan.
R. p. tantilla Riley, 1935 - N Philippines (Luzon).



Descriptive notes. 12 cm; 9·5-17 g. Nominate race is somewhat variable in overall coloration, but typically olive-brown above, with wings and tail dark brown; chin, throat and breast grey-brown, abdomen and undertail-coverts dull white; underwing-coverts grey-brown; tail square-ended. Distinguished from *R. riparia* and *R. diluta* by brown throat, no breastband, no feathers on tarsus, from *Ptyonoprogne* species by small size and lack of white in tail, and from *Phedina* martins by unstreaked belly. Sexes alike. Juvenile has buffy feather edges. Races separated by size and by shade of brown, but differences slight, and much individual variation: *mauritanica* is small and pale; *minor* is small, with dark upperparts; *schoensis* is larger and dark; *newtoni* is also dark, with greyer throat and breast and extensive white on abdomen; *ducis* is dark, with blackish crown and little white on abdomen; *cowani* is small, with greyer underparts and grey-white throat; *chinensis* is small, with pale grey-brown upperparts and throat; *tantilla* is similar to last, but has darker rump. Voice. Weak twittering song; calls include a contact call "svee-svee", a flock call "skrrr", a low "chee, wer-chi-cho wer-chi-cho" between mates during nest-burrowing, a "chi-choo" on arrival at nest with young, and a harsh alarm call.
Habitat. Near rivers, lakes and other waterbodies, especially in breeding season. Also forages over grassland, bush, sand dunes, sewage works, reedbeds, wetlands, rice fields, and estuaries. Wide altitudinal range: from sea-level mainly to 3000 m in E Africa, but to 3700 m in E DRCongo (Mt Karisimbi); 500-1800 m in Madagascar; mainly to 1000 m in China and 1500 m in Indian Subcontinent, but locally to 4600 m. Non-breeding flocks roost in reedbeds.
Food and Feeding. Diet includes dipteran flies such as chironomids, tipulids, syrphids and muscids, Hymenoptera (ants), homopteran bugs (aphids), beetles (Coleoptera), dragonflies (Odonata) up to 25 mm long; grasshopper (Orthoptera) also recorded. Feeds in flocks, often of c. 20 individuals, sometimes hundreds, often with other hirundines, e.g. *R. riparia*; usually over water at average height of 14 m, but also close to water's surface. Flight weak and fluttering. Often feeds late in evening. Visits grass fires in S Asia.
Breeding. Season variable, probably depending on rains, generally in dry season in S Africa, in rains in E Africa; Oct and Dec-Mar in Morocco, Oct-Feb in Nigeria, almost any month in Ethiopia, mainly Mar-Jul in E Africa, Jun-Sept in Zambia and Zimbabwe, Jun-Jul in Malawi, Nov-Dec in Mozambique; breeds most months in South Africa (mainly Feb-Oct in Free State, KwaZulu-Natal and in E, and peaks Sept-Dec in SW Cape and Nov-Jan in E Cape); Nov-Apr in Madagascar; mainly Oct-Feb, rarely to May, in Indian Subcontinent, but Feb-Nov in Nepal; Jun-Aug in Tadjikistan; Mar-May in Philippines. Usually in small groups of c. 3-12 pairs, once 137, and up to 500 pairs reported, burrows close together; occasionally solitary; sometimes breeds with *R. riparia*. Copulation on the ground recorded. Burrow dug by both sexes, taking turns, completed in c. 3 weeks, usually 30-80 cm long, sometimes over 150 cm, 0·8-3 m above ground in bank of e.g. river, lake, road, quarry, pit, gorge or mine dump; old hole of starling (Sturnidae) or bee-eater (*Merops*) sometimes used, and one nest recorded in drainage pipe; enlarged nest-chamber lined with grass, hair and feathers. Clutch 2-4 eggs, but 3-5 in Madagascar and up to 5 or 6 in India; incubation by both sexes, mainly by female, period c. 12 days; both also feed chicks, which leave nest at c. 20-25 days; fledglings remain with parents for some days. Recorded longevity in wild c. 5 years.
Movements. Sedentary in some areas, e.g. Morocco; partial migrant in others, e.g. E & S Africa. Forms large flocks after breeding. In Zimbabwe, Jun-Sept breeding population replaced by migrants in austral winter. Post-breeding dispersal, especially from flooded sites, rather than regular migration, is usual, e.g. in Sudan moves S after breeding; makes local movements in Pakistan, India and Bangladesh; where present all year, numbers often fall in non-breeding season. Migratory in SC Asia (S Tadjikistan), absent Sept-May. Vagrant in several countries, e.g. Egypt, Israel, Saudi Arabia, Oman.
Status and Conservation. Not globally threatened. Common in most of range. In Africa, common in some areas, as in Morocco, where range has recently increased near Rabat, and in S Africa, especially SW Cape; often locally abundant when suitable breeding sites present, e.g. in Ethiopia and E Africa. Generally common and widespread in Asia. Probably benefits from using some artificial nest-sites, but adversely affected by wetland drainage, dam construction and regulation of river flows.

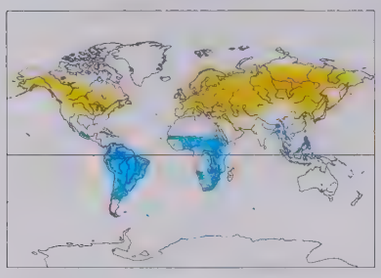
13. Congo Sand Martin

Riparia congica

French: Hirondelle du Congo **German**: Kongouferschwalbe **Spanish**: Avión del Congo
Other common names: Congo Martin

Taxonomy. *Cotile congica* Reichenow, 1887, Manyanga, lower River Congo, DRCongo.
May be derived from *R. riparia*. Forms a superspecies with that and with *R. paludicola* and *R. diluta*. Monotypic.
Distribution. R Congo and lower R Ubangi, on PRCongo-DRCongo border.

Descriptive notes. 11 cm. Has grey-brown head and upperparts, dark brown wings and tail, tail almost square; upper breast light brown, rest of underparts white; underwing-coverts dark brown. Differs from *R. riparia* in smaller size, less well-defined breastband; from *R. paludicola* in paler throat. Sexes alike. Juvenile has pale feather tips on upperparts, less distinct brown breastband. Voice. Unknown.
Habitat. Riverine, but also feeds over forest.
Food and Feeding. Details of diet not known. Flight fast and fluttery, with rapid shallow wingbeats. Will feed with other swallows, especially *R. riparia*.
Breeding. When river level low, exposing sand; breeds in Feb-Mar near Lukolela. Colonial; sometimes nests near *Pseudhirundo griseopyga*. Digs own burrow in sandbar or steep side of sandy island. Clutch size and incubation and fledging periods not recorded.
Movements. Probably resident, although some individuals caught near Mbandaka, in DRCongo, thought to be migrants.
Status and Conservation. Not globally threatened. Locally common to abundant within its limited range, but few seen along R Ubangi. Recorded also along R Sangha, in PRCongo, but status there uncertain.
Bibliography. Bannerman (1953), Borrow & Demey (2001), Chapin (1953), Demey *et al.* (2000), Dowsett (1989), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Keith *et al.* (1992), Lippens & Wille (1976), Louette (1992), Lynes (1938), Mackworth-Praed & Grant (1973), Pedersen (2000), Sinclair & Ryan (2003).



14. Collared Sand Martin

Riparia riparia

French: Hirondelle de rivage **German**: Uferschwalbe **Spanish**: Avión Zapador
Other common names: Common/European/Gorgeted Sand Martin; Bank Swallow (America)

Taxonomy. *Hirundo riparia* Linnaeus, 1758, Europe = Sweden.
Forms a superspecies with *R. paludicola*, *R. congica* and *R. diluta*. Until recently considered conspecific with last, but the two differ in plumage and voice, and occur in separate breeding colonies in wide area of sympatry (full extent of which not yet clear). Described race *kolymensis* (E Siberia) merged with nominate and *taczanowskii* (L Baikal area and C Mongolia E to Ussuriland) with *ijimae*, but both possibly distinguishable; proposed taxon *dolgushini* (from SE Kazakhstan) is synonym of *innominata*. North American populations sometimes considered to represent a separate, supposedly smaller, race *maximiliani*, but differences from Eurasian birds negligible. Five subspecies recognized.
Subspecies and Distribution.
R. r. riparia (Linnaeus, 1758) - North America from W & C Alaska and Canada (N Yukon, NW & SC Mackenzie and N Saskatchewan E to S Labrador and SW Newfoundland) S in USA to C California, W Nevada, Utah, N & C New Mexico, NE Oklahoma, N Alabama, C West Virginia, E Virginia, and casually NW N Carolina and SC South Carolina, also SC Texas and NE Mexico (N Nuevo Léon, N Tamaulipas); Eurasia from Ireland, Britain and N Scandinavia E through Siberia (E to about R Kolyma and Kamchatka), S to N Mediterranean, Turkey, Syria, Iraq, SW Iran and C Asia; has bred locally in NW Africa. Winters South America and Africa.
R. r. innominata Zarudny, 1916 - SE Kazakhstan; may winter in Africa or in SW or S Asia.
R. r. ijimae (Lönnberg, 1908) - L Baikal area and C Mongolia E to Sakhalin, N Japan (Hokkaido) and Kuril Is; reported as breeding also in NE India (Assam), but review required. Winters SE Asia, including Philippines.
R. r. shelleyi (Sharpe, 1885) - Egypt (Nile Valley); winters S to Sudan and Eritrea.
R. r. eilata Shirihai & Colston, 1992 - breeding range not known; recorded on passage in Israel.
Descriptive notes. 12 cm; 11·19·5 g. Combination of small size, white chin and throat and well-demarcated dark breastband distinctive. Nominate race is earth-brown or grey-brown above,

On following pages: 15. Pale Sand Martin (*Riparia diluta*); 16. Banded Martin (*Riparia cincta*); 17. Tree Swallow (*Tachycineta bicolor*); 18. Violet-green Swallow (*Tachycineta thalassina*); 19. Golden Swallow (*Tachycineta euchrysea*); 20. Bahama Swallow (*Tachycineta cyaneoviridis*); 21. Tumbes Swallow (*Tachycineta stolzmanni*); 22. Mangrove Swallow (*Tachycineta albilinea*); 23. White-winged Swallow (*Tachycineta albiventer*); 24. White-rumped Swallow (*Tachycineta leucorrhoa*); 25. Chilean Swallow (*Tachycineta meyeni*).

upperparts with pale feather tips in fresh plumage; remiges and rectrices darker brown with faint green sheen, tail shallowly forked; underparts white, with broad brown breastband (can extend down centre of belly); underwing-coverts dark brown; tuft of feathers on hind toe at joint with base of tarsus. Distinguished from similar *R. diluta* by darker and less grey upperparts, more distinct breastband; from *R. cincta* by smaller size, lack of white supercilium. Sexes alike. Juvenile has pale feather edges on upperparts, cinnamon to rufous-buff wash on lores, cheeks, neck side and chin to breast, and buff or cream tinge on lower underparts. Race *innominata* is smaller, paler and greyer than nominate, with less clearcut breastband; *ijimae* is darker brown; *shelleyi* is smaller and paler, with narrow breastband; *eilata* is small, with buff-brown chin, brown mottling on throat. Voice. Song is a harsh twittering; calls include a harsh contact call "tschr", high- and low-pitched alarm calls, an excitement call "schrrp", and calls uttered to young.

Habitat. Mainly lowland, open country, especially near water, breeding along coasts, rivers and streams, and at lakes and reservoirs, sometimes close to or within areas of human habitation. Breeding habitat ephemeral; suitability of sites depends on erosion, which both creates new sites and destroys established ones. Also, prefers new, fresh banks without old burrows. Forages over waterbodies, grassland, farmland, occasionally woodland. Often roosts in reedbeds.

Food and Feeding. Mostly insects, some spiders. Diet varies within and between years and sites, depending on local availability of insects. In North American study, diet consisted of 33% Hymenoptera, 27% flies (Diptera), 18% beetles (Coleoptera), 10% mayflies (Ephemeroptera), 8% hemipteran bugs, 2% Odonata and 1% Lepidoptera; in Scotland, 69% Diptera, 13% hemipterans and psocids (Psocoptera), 11% Coleoptera, 5% Hymenoptera. For adults in North America, 28% hemipterans, 21% Coleoptera, 20% Diptera, 17% Hymenoptera, 4% spiders (Araneae) and 1% stoneflies (Plecoptera); for nestlings, 34% Hemiptera, 20% Diptera, 18% Coleoptera and 17% Hymenoptera. Nestlings in Scotland fed 37% Diptera (mainly Nematocera), 33% Ephemeroptera, 26% Hemiptera and Psocoptera (mainly aphids), and a few Coleoptera, Hymenoptera, lacewings (Neuroptera), caddis flies (Trichoptera), Lepidoptera and spiders. Forages alone or in small or large groups, on average 15 m above ground, but in adverse weather usually low over water. Mixes freely with other hirundines. Flight fast and fluttery, with shallow and rapid wingbeats. Sometimes follows tractors, and occasionally takes insects from ground or water, especially when these form large concentrations; recorded as taking maggots dropped on ground by anglers. When breeding, forages mostly close to nest; in Scotland, fed up to 1 km from colony, with average distance 190 m.

Breeding. Mainly late Apr to Aug; two broods in most of range, but one in far N & E, and one appears to be usual in North America. Socially monogamous, but extra-pair paternity occurs (in Scottish study 36% of 45 broods, 14% of nestlings; in Hungarian study 40% of 22 broods, 24% of nestlings); also, male's extra-pair mate will lay in his nest (in Scottish study 9% of broods, 2·4% of nestlings), but no evidence of this in Hungarian study; occasionally changes mate, nest-hole or colony for second brood. Colonial, burrows close together, average 18·5 cm apart (range 10·2-43·2 cm, 20 colonies) in one study, 13·2 cm (1-59 cm, 32 colonies) in another, with small area around burrow entrance defended; colonies often over 100 pairs, sometimes thousands, but majority fewer than 50 pairs, average size of 1222 colonies in Hungarian study was 198 pairs (range 1-3179) with, over 12-year period, 20-60% of population in colonies of over 1000 pairs; breeding synchronous within subgroups of colony. Male initiates burrow-excavation; when burrow at least 30 cm deep, attracts female by singing and flying in circles around entrance, then perches at or hovers in front of it and displays throat patch; sings, sometimes quivering wings, before mounting female, copulations occur in nest, on ground, on wires and on bank face; males frequently chase females to mate with them, also closely follow own mate when she is fertile. Burrow dug by both sexes, mainly male, over 4-5 days, digging rate varies with soil type (in Alaska, c. 3 cm per day in gravel to c. 13 cm per day in coarse soil with gravel); length c. 50-100 cm, average 58-90 cm in various studies, shorter in compact sand and gravel soils than in loose sand, silt or loam, also shorter later in season; breeding more successful in deep burrows; sites include banks of rivers, streams and lakes, sandy cliffs and dunes, sand and gravel quarries, road and railway cuttings, occasionally other artificial sites (e.g. cut peat, building-site excavations, colliery slag heaps, sawdust piles); artificial tunnels such as drainage holes in concrete banks, drainpipes, and holes in walls sometimes used; readily colonizes newly exposed sites; large colonies tend to be in artificial sites or along long banks, e.g. for Hungarian colonies of over 1000 pairs average length of riverbank was 209 m; height of banks used c. 2-3 m (range 0·5-7·6 m), in Saskatchewan (Canada) study higher than banks not used for breeding (1·8 versus 1·4 m), and in England burrows higher in quarries (3·9 m) than in riverbanks (1·8 m); usually nests in upper third of bank; sometimes burrows in horizontal surface, on islands without ground predators; generally, new burrow excavated each season, but old burrow sometimes enlarged and reused; nest of grass, rootlets, plant stalks, leaves and feathers constructed at end of burrow, mainly by female, taking 1-3 days (total time for burrow and nest up to 14 days), feathers added during laying and incubation (and sometimes after hatching), old nests in reused burrows often thrown out and replaced. Clutch 3-6 eggs, typically 4 or 5 (occasionally 2 or 7), clutch size decreasing from N to S and during course of season, e.g. in Britain 45% of 56 clutches were of 5 eggs, 27% of 4, 21% of 6 and 7% of 2-3, and in Hungarian study mean clutch size decreased from 5·78 early in season and 5·46 at peak to 4·68 late in season; egg-dumping by conspecifics recorded (in Scotland only 4% of broods, 1·8% of nestlings, but in Hungary 36% of broods, 11% of nestlings); incubation starts 1-2 days before clutch complete, by both sexes, usually female at night; contribution of male (which lacks brood patch) during day varies, about half of incubation in one study, a third and with shorter bouts (male 7·7 minutes, female 13·8 minutes) in another; incubation period 12-16 days, mostly 14-15 days; eggs hatch over 1-3 days; chicks brooded almost continuously for first few days, brooding declining to c. day 7-10, depending on weather; fed by both sexes, feeding rates varying with weather and with brood size and age, typically 20-30 visits per hour in good weather; by c. 9 days of age nestlings rush to meet parents returning with food, and from c. 15-17 days wait at burrow entrance; fledging period averages 22·3 days in Scotland, only 18·7 days in North America; fledglings return to burrow for 4-5 days, fed by parents for up to a week, form crèches during day and roost in burrows, often not their own. Breeding success 54-78% in various studies; in one study, burrows longer than 70 cm had 73·2% success, while figure for those of 70 cm or less was 50·9%; causes of losses include adverse weather, predation and collapse of nest-site; along R Tisza, in Hungary, flooding every 12-15 years leads to loss of first clutches of c. 20,000 pairs; ectoparasites in reused old nests also reduce breeding success. Recorded longevity 9 years.

Movements. Migratory. Forms flocks and roosts of hundreds or thousands after breeding, roosts of up to c. 2 million individuals recorded. Adults gather at communal roosts and migrate soon after breeding; juveniles prone to wander over large area, moving between roosts. Migrates and roosts with other hirundines. N populations are long-distance migrants: those in North America migrate to South America, mainly S to N Argentina, Paraguay and N Chile, but recorded as far S as Brunswick Peninsula (S Chile), also irregularly in winter in W Mexico; Eurasian breeders winter mainly in Afrotropics, principally in Sahel zone (E from Senegal) and in E Africa S to Mozambique. Routes mainly over land or along coasts with short sea crossings, but in America include West Indies (rare in Lesser Antilles). Autumn migration early Aug to late Sept; present mainly Oct-Mar on wintering grounds, where widespread but sparsely distributed; in Africa most abundant in E & C areas, E breeding populations extending farther S than do W ones; British breeders appear to move E through Sahel during winter and return by a more easterly route than in autumn. Spring passage in E Mediterranean peaks late Apr to early May, in W Mediterranean early Apr; in Middle America and S USA early Mar to May; in N of range mid-Mar to mid-Jun. Males arrive back on breeding grounds before females, and first-years up to 2-3 weeks later than adults; return to same colony in subsequent years, adults more so than first-years, e.g. in Britain 93% of adults and 87% of first-years returned to within 10 km of site where ringed. E Asian race *ijimae* probably winters mainly in S China and SE Asia; uncommon as far S as Malay Peninsula and rare in Philippines, and also recorded in NW India. Egyptian race *shelleyi* moves relatively short distances, as far as S Sudan and NE Ethiopia. Non-breeding range of Kazakhstan race *innominata* uncertain, likely to be in Africa or in SW or S Asia. Species is widespread as a vagrant, with records from, for example, N Alaska, Commander Is, Aleutian Is, Atlantic Ocean (e.g. Faeroes, Madeira, Cape Verde Is, Barbados, Falklands) and New Guinea.

Status and Conservation. Not globally threatened. Generally fairly common to common in most of range. Race *eilata* virtually unknown; recorded only in Israel, on passage, and neither breeding nor non-breeding ranges known. In 1990s, population in Europe and Russia estimated to be c. 2,800,000-14,000,000 breeding pairs. Population trends difficult to determine because of ephemeral nature of breeding sites, movement of individuals between areas, and variable survival rate during migration and winter period; Russian population thought to be stable, that in Sweden thought to fluctuate on cycle of c. 12 years. Droughts in wintering areas, which reduce foraging habitat and food supply, have been associated with severe large-scale population declines in W Europe in 1970-1990, particularly in 1968/69 and again in 1983/84; in 1984, British population c. 10% of peak size in mid-1960s; in studies in Hungary, adult survival rate was related mainly to rainfall in E Africa and Nile Valley during spring migration, although size of local breeding population was dependent on immigration and emigration. North American populations appear largely stable, but declines reported in California (where species listed as "Threatened") and Kentucky (where a Species of Special Concern). Although this species is widespread, suitable breeding sites are localized and often ephemeral, and breeding habitat also often lost through human activities (e.g. flood control and erosion control on rivers), but, conversely, road-building and sand and gravel quarries provide new, albeit often temporary, sites; such activities have led to local changes in range, in North America e.g. contraction in California and expansion in British Columbia, and local declines, as in Connecticut and Virginia. In Europe, because of management of waterways, is largely dependent on artificial breeding sites such as quarries; use of artificial sites in North America variable, only 5% of 111 colonies in California but 96% of 25 colonies in Pennsylvania and Vermont. Number of colonies in Hungary was related to area of suitable nesting habitat. Ideally, needs fresh banks for breeding (to avoid ectoparasites in used nests), and long areas of riverbank that can accommodate large colonies (i.e. of over 1000 pairs), which can hold up to 60% of local population and allow rapid recovery after losses in non-breeding period. Can be attracted to artificially constructed tunnels. On breeding grounds, feeding habitat may also be lost by the use of pesticides on farms.

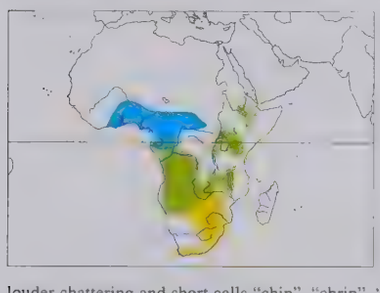
15. Pale Sand Martin

Riparia diluta

French: Hirondelle pâle **German**: Fahluferschwalbe **Spanish**: Avión Pálido
Other common names: Pale Martin

Taxonomy. *Cotile diluta* Sharpe and Wyatt, 1893, Chimkent, north of Tashkent, Kazakhstan.
Forms a superspecies with *R. paludicola*, *R. congica* and *R. riparia*. Until recently considered conspecific with last, but differs morphologically and vocally, and found in separate breeding colonies in wide area of sympatry (full extent of which not yet clear). Six subspecies recognized.

Subspecies and Distribution.
R. d. gavrilovi Loskot, 2001 - breeds C Siberia E to R Lena, and Cisbaikalia S to Altai and Tuva Republic.
R. d. transbaykalica Goroshko, 1993 - breeds Transbaikalia.
R. d. diluta (Sharpe & Wyatt, 1893) - S & SE Kazakhstan; winters NW India and Nepal.
R. d. indica Ticehurst, 1916 - Pakistan and N India.
R. d. fohkienensis (La Touche, 1908) - C & E China.
R. d. tibetana Stegmann, 1925 - SW China (Xizang-Qinghai Plateau).



Descriptive notes. 12 cm. Nominate race is pale grey brown above, remiges and rectrices darker brown, tail shallowly forked; underparts dingy white, weakly defined pale brown breastband; underwing brown; hind tarsus feathered. Distinguished from similar *R. riparia* by paler and greyer upperparts, rather dingier underparts with less well-defined breastband. Sexes alike. Juvenile has pale feather edges on upperparts. Races separated by size, N populations being larger, and by depth of colour of upperparts and size and colour of breastband: *gavrilovi* has darker upperparts than nominate, and darker, more clear-cut breastband; *transbaykalica* is large, with dark upperparts with reddish tint, browner head; *indica* is small; *fohkienensis* is also small, but larger than previous, and dark; *tibetana* is darker than nominate. Voice. Song is a short, grating twittering; when flying around breeding colony, makes a hard "ret" or "brrit".
Habitat. Mainly open country, often near water; in area of sympatry with *R. riparia* in arid steppe, farther from water sources than latter. Up to c. 4500 m in Himalayas. Roosts in reedbeds.
Food and Feeding. Diet not fully documented, probably similar to that of *R. riparia*. Forages in groups, and mixes with other hirundines and swifts (Apodidae). Fast and fluttery flight, with shallow, rapid wingbeats.
Breeding. Nov-May, mainly Feb-Apr. Colonial, usually small colonies, up to c. 150-200 nests. Nest in burrow in bank, e.g. along stream or river, at lake or in road cutting, nest of grass and feathers at end of burrow. Clutch 3 or 4 eggs in India, 4-7 in China; no further information.
Movements. N populations migratory, but wintering sites poorly known; nominate race probably winters mainly in N India, but recorded as far W as Egypt; *fohkienensis* winters in S China. Reported from NE Vietnam; may winter more widely in SE Asia, but possibly not recognized as being distinct from *R. riparia* (of race *ijimae*).
Status and Conservation. Not globally threatened. Locally common. Both breeding and non-breeding distributions poorly known, require further study. Breeding sites probably local and ephemeral as for *R. riparia*, and affected by similar factors, such as flooding of nests.
Bibliography. Abdulali (1975b), Ali & Ripley (1987), Caldwell & Caldwell (1931), Carey *et al.* (2001), Cramp (1988), Dementiev *et al.* (1968), Dickinson & Dekker (2001b), Étchécopar & Hüe (1983b), Gavrilov & Savchenko (1991), Goroshko (1993), Grimmett *et al.* (1998), Hagemeijer & Blair (1997), Inskipp & Inskipp (1991), Loskot (2001), Loskot & Dickinson (2001), MacKinnon & Phillipps (2000), Ripley (1982), Roberts (1992), Robson (2000), Stuart Baker (1934).

16. **Banded Martin**

Riparia cincta

French: Hirondelle à collier **Spanish**: Avión Cinchado
German: Weißbrauen-Uferschwalbe
Other common names: Banded Sand Martin

Taxonomy. *Hirundo Cincta* Boddaert, 1783, Cape of Good Hope, South Africa.
Relationship to others in genus not clear; has sometimes been placed in a monotypic genus *Neophedina* on basis of its large size, bill and nostril shapes, loral bristles, squarer tail and more solitary lifestyle. Initial DNA-DNA hybridization studies also did not support a close relationship, but cytochrome *b* data suggest that this species and *R. riparia* are sister-taxa. Five subspecies recognized.
Subspecies and Distribution.
R. c. erlangeri Reichenow, 1905 - Ethiopia.
R. c. suahelica van Someren, 1922 - S Sudan, E & SE DRCongo, Uganda, W Kenya, Rwanda, Burundi, NW & S Tanzania, Zambia, Malawi, N Zimbabwe and W Mozambique.
R. c. parvula Amadon, 1954 - N Angola (N Bengo E to Lunda Norte), SW DRCongo and NW Zambia, possibly also S Gabon and S PRCongo; migrates N at least to Cameroon.
R. c. xerica Clancey & Irwin, 1966 - W & S Angola (Cabinda, and S Bengo and Luanda E to S Lunda Sul and Moxico and S to Huíla), N Namibia and N Botswana, possibly also NW Zimbabwe.
R. c. cincta (Boddaert, 1783) - S Zimbabwe, SE Botswana, South Africa, Lesotho and Swaziland; migrates N at least to Angola and DRCongo.

Descriptive notes. 17 cm; 19-30 g. Has blackish lores and line through eye, white stripe from base of bill to above eye; crown and upperparts, including wings and tail, dark brown, tail square; underparts white, brown breastband. Differs from *R. riparia* in larger size, white supercilium. Sexes alike. Juvenile has rufous to cream feather edges on upperparts, pale breastband. Races differ in size and in shade of brown: *erlangeri* is larger than nominate, has narrower breastband; *suahelica* is darker; *xerica* is pale; *parvula* resembles last, but has broader breastband. Voice. Song is a squeaky warbling, sometimes ending in a trill; also a louder chattering and short calls "chip", "chrip", "kip".
Habitat. Open country, such as grassland, savanna, cultivation, often near water. Up to 3000 m. Roosts in reedbeds.
Food and Feeding. Diet includes beetles (Coleoptera), moths and their caterpillars (Lepidoptera), flies (Diptera), mantids (Mantodea), lacewings (Neuroptera). Forages alone or in small groups, sometimes with other swallows and swifts (Apodidae); flight slow and deliberate. Feeds around large animals; attends grass fires. Occasionally takes insects, such as caterpillars, plucking them from vegetation.
Breeding. May-Aug in Ethiopia, Feb-Jun and Aug-Sept in E Africa, Jul in DRCongo, mostly Nov-Dec in Angola, and Aug, Oct and Dec-Jan in Zambia; mainly Sept-Apr in S, with early peak in SW Cape. Solitary. Digs burrow in vertical bank, e.g. along river or embankment, near water, burrow usually c. 60-90 cm long, but 40-50 cm recorded in hard ground; roof of aardvark (*Orycteropus afer*) burrow, disused starling (Sturnidae) burrow and drainage pipe also occasionally used; nest-chamber lined with grass and feathers. Clutch 2-5 eggs, 2-4 in S Africa; incubating bird said to be fed by mate, incubation period not recorded; both sexes feed chicks, one visit every 10 minutes, fledging period 21-24 days. Longevity at least 4 years.
Movements. Mainly resident, with some poorly known local movements; S populations migratory. Post-breeding flocks of tens of birds, once c. 1000. Breeding visitor to S Africa, present mainly Sept-Apr, but Aug-Feb in SW Cape and to late May/early Jun in EC areas; passage N in Zimbabwe and Botswana Apr-May, return passage less obvious; some overwinter in breeding range, especially in N, e.g. present all year in N Botswana (nomadic in Okavango). Non-breeding visitor to W Africa, mainly May-Oct, although some suggestion of breeding as well. Nominate race migrates N at least to Angola and DRCongo after breeding, is an uncommon visitor in W Africa; *erlangeri* is resident, although reported a few times from Kenya; *suahelica* is mainly resident, but is a breeding visitor to Zimbabwe; *parvula* migrates N at least to Cameroon, possibly W Africa; *xerica* non-breeding sites not known, may be resident, or may migrate, possibly to W Africa, and be replaced by other migrants. Vagrants recorded in Egypt and N Yemen.
Status and Conservation. Not globally threatened. Generally uncommon and local; locally common in parts of E Africa and frequent in Ethiopia; widespread in grasslands of Swaziland and S Africa, where common in E. Does not use artificial sites to any great extent; has probably benefited little from presence of humans, although agricultural development may provide new breeding areas, e.g. in SW Cape.
Bibliography. Aspinwall (1983), Bannerman (1939, 1953), Benson & Benson (1977), Benson *et al.* (1971), Borrow & Demey (2001), Britton (1980), Byaruhanga *et al.* (2001), Christy & Clarke (1994, 1998), Clancey (1964b, 1966c), Clancey & Irwin (1966), Clements (1990), Critchley (1975), Dean (2000), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1973), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Irwin (1981), Jones & Tye (1988), Keith *et al.* (1992), Lewis (1989), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993a), van der Merwe (1986), Nikolaus (1987), Penry (1994), Rand *et al.* (1959), Roberts, A. Genus *TACHYCINETA* Cabanis, 1850

17. **Tree Swallow**

Tachycineta bicolor

French: Hirondelle bicolore **German**: Sumpfschwalbe **Spanish**: Golondrina Bicolor

Taxonomy. *Hirundo bicolor* Vieillot, 1808, New York, USA.
Has been placed with *T. albilinea* (and, by extension, *T. stolzmanni*), *T. albiventer*, *T. leucorrhoa* and *T. meyeni* in separate genus *Iridoprocne*. DNA studies, however, indicate close relationship of these with clade consisting of *T. thalassina*, *T. euchrysea* and *T. cyaneoviridis*, and support placement of all these taxa in a single genus. One record of hybridization with *Petrochelidon pyrrhonota*. Monotypic.
Distribution. N & C North America from W & C Alaska and Canada (N Yukon, NW & S Mackenzie, N Saskatchewan and Manitoba E to NC Quebec, C Labrador and Newfoundland) S in USA to S California, C Nevada, N Arizona, N New Mexico, Texas (irregular), N Alabama, N Georgia and North Carolina (casual in NE Louisiana and Mississippi); winters mainly S USA coasts and West Indies S to N coast of South America.

Descriptive notes. 14 cm; 17-25·5 g. Male is glossy blue-green above, wings and tail blackish, tail shallowly forked; underparts white, underwing-coverts grey-brown. Differs from *T. thalassina* in glossy plumage, no white above and behind eye, no white on rump side. Female is duller than male, sometimes with brown forehead. Juvenile has brown upperparts and grey-brown wash on breast, resembles *Riparia riparia* but larger, without distinct breastband; first-year female is brown above with variable number of blue feathers, a few 2-year-old females still having some brown feathering. Voice. Large vocal repertoire: "dawn song" is a repetition of a few phrases sung around dawn by males in flight above and at nest-site; during the day, song is briefer and less continuous; calls include a contact call "buli-dulidulit", a nest-site advertising call "she-she-she-shet", an alarm call "peeh" or "pee-deeh", a distress call "zhjizhj", a gurgling call uttered by male to mate, an anxiety call "euree", aggressive calls "zjiht" and "tick-tick-tick", a submission call "tee", a pair interaction call and a copulation solicitation call "chi-chit".
Habitat. Open areas, especially near water, such as lakes, marshes and ponds; requires trees with suitable holes for nesting (but also breeds N of tree-line, in nestboxes). Feeds over water and fields, often in lee of wind. Roosts in marshes, trees.
Food and Feeding. Mostly insects, also molluscs, spiders; some fruits. In samples taken throughout North America, diet consisted of 40% flies (Diptera), 14% beetles (Coleoptera) and 6% ants (Hymenoptera). Nestling diet in New York State c. 58% dipteran flies (Nematocera, Brachycera), c. 18% hemipteran bugs and c. 14% Odonata; in various studies in Ontario, 46-53% Diptera, 9-26% homopteran bugs, 11-16% mayflies (Ephemeroptera), 4-5% Odonata, 2-4% beetles, 2-4% Mollusca, and a few psocids (Psocoptera), hymenopterans, hemipterans, lacewings (Neuroptera), caddis flies (Trichoptera), Lepidoptera and spiders (Araneae); at other sites up to 90% Diptera. Prey mainly 1-10 mm (up to 60 mm). Nematocerans, especially Chironomidae, important, 44-92% of nestling diet in various studies; in acidic wetlands, more aquatic dipterans and fewer ephemeropterans taken. Also eats seeds and berries, mainly of bayberry (*Myrica*), especially in autumn, winter and spring; large flocks, some of more than 50,000 individuals, strip shrubs in a few minutes. Birds wintering on Long I (New York) had eaten mainly crustaceans, as well as water boatmen (Heteroptera), spiders, and seeds of bulrush (*Typha*), sedge (Cyperaceae), bayberry and smartweed (*Polygonum hydropiper*). Forages singly or in groups; large numbers sometimes gather at insect swarms. Flies 0-50 m or more above ground, and mostly within 4 km of nest-site; when feeding nestlings, usually 100-200 m from nest and up to 12 m above ground. Flight a mix of flapping and gliding. Will take insects from ground, water, vertical surfaces and vegetation.
Breeding. Laying mainly early May to mid-Jun, earlier in S of range than in N, fledging mid-Jun to Jul; single-brooded. Socially monogamous, but 0-8% of breeding males polygynous and extra-pair

paternity very common (38-69% of nestlings in 50-87% of broods, and broods often contain nestlings sired by several males; female apparently actively selects or rejects extra-pair males). Solitary, or in loose groups with nests usually at least 10-15 m apart; both sexes defend extra nest-sites in territory. Courtship includes vertical display posture by male; responsive female supplants male on perch, male goes to nest-hole and gives high-pitched call; copulation on perch near nest; male does not guard mate during her fertile period. Nest a hollowed-out pad of grass, pine needles, moss and aquatic plants, cup lined with feathers, material brought mostly by female; in pre-existing hole, usually in tree, sometimes in pipe, fence post or other artificial site, nestboxes frequently used. Clutch 2-8 eggs, usually 4-7, mean 5·4, clutch size declines through season; incubation by female alone, period 11-19 days, usually 14-15 days; hatching usually synchronous, but in poor weather asynchronous with resultant weight hierarchy among young; chicks fed by both parents, c. 10-20 feeds per hour, male provisions less than female, and polygynous males feed only brood of first mate; fledging c. 18-22 days. Average hatching success c. 88%, fledging success c. 80%, slightly lower for yearling females than for older ones and reduced by poor weather; in Saskatchewan (Canada) nestbox study, only 27·7% of nests fledged any young in a year with cold wet weather, compared with 62% in a hot dry year and peak of 89·6% in a third year; hatching success and nestling growth also poorer in acidic wetlands; also, availability of nest-sites often limited, competition for breeding opportunities sometimes leads to infanticide; annual mortality 79% in first year, 40-60% subsequently. Longevity 12 years.

Movements. Migratory. Large post-breeding flocks, sometimes hundreds of thousands in roosts. Normal winter range extends from W California and SW Arizona and, in E, from S New Jersey, S Florida (irregular Florida Keys) and Gulf coast, S to Mexico and, in smaller numbers, to Panama and NW coast of South America, in Caribbean including N Bahamas, Greater Antilles, Cayman Is, Swan Is (N of Honduras); sometimes winters along US Atlantic coast as far N as New York (Long I) and E Massachusetts. Possibly resident in S California. Migration peaks in early to mid-autumn; birds from E coast and E Great Lakes probably migrate down Atlantic coast to winter mainly in Florida and Caribbean; those from Canadian prairies and Midwest may move through Mississippi Basin to Gulf coast and Central America. Returns early in spring, mid-Mar to early Apr; 13-60% of breeding adults return to same area to breed; females less site-faithful than males, especially after breeding failure, will move to locality 15-30 km from previous one. Vagrants recorded within Arctic Circle (N to Seymour I and Banks I, Keewatin and Boothia Peninsula, also Wrangel I), in extreme N Pacific (St Lawrence I, Pribilof Is, Aleutian Is), in Greenland, in mid-ocean at Clipperton Atoll (W of Central America), and in Europe (Britain).

Status and Conservation. Not globally threatened. Total population estimated at c. 20,000,000 birds. Abundant in E Canada and NE USA (New England and Adirondack Mts). Since 1980, range has extended S in parts of USA (Texas, Oklahoma, Missouri, Arkansas, Kentucky, Tennessee, Alabama, Georgia, N Carolina), believed facilitated by changes in land use (e.g. reservoir creation), reintroduction of beavers (*Castor canadensis*), and provision of nestboxes for bluebirds (*Sialia*), which this hirundine also exploits. Population probably limited by availability of nest-sites; nestboxes can increase numbers locally (e.g. in Virginia and Kentucky), but species probably also adversely affected by forest clearance and removal of dead trees and subsequent loss of natural sites. Suffers from competition for nest-sites with introduced Common Starling (*Sturnus vulgaris*) and House Sparrow (*Passer domesticus*). Drainage of marshes reduces suitable habitat in wintering areas. Possibly adversely affected by acid rain, as acidity of wetlands influences type of prey available, in particular calcium-rich items. Pesticides and pollutants, acquired from insect food, sometimes reach high concentrations in the birds and their eggs; few effects on breeding success recorded, but PCB contamination has been associated with adults abandoning eggs, fewer eggs hatching, and possibly poor nest quality. Severe cold weather leads to high mortality in winter and spring.

18. Violet-green Swallow

Tachycineta thalassina

French: Hirondelle à face blanche **German**: Veilchenschwalbe **Spanish**: Golondrina Verdemar

Taxonomy. *Hirundo thalassinus* Swainson, 1827, Real del Monte, Hidalgo, Mexico.
Closely related to *T. euchrysea* and *T. cyaneoviridis*. Population from Alaska and Canada S to Arizona, New Mexico and Baja California sometimes treated as separate race *lepida*. Two subspecies recognized.

Subspecies and Distribution.
T. t. thalassina (Swainson, 1827) - C Alaska and W Canada (S from N Yukon, SW Mackenzie, N British Columbia, WC Alberta, SW Saskatchewan) S in W USA (E to W North Dakota and NW Nebraska) to S Arizona and S New Mexico, and Mexico (S to C Baja California, also on plateau S to Oaxaca and Veracruz); winters Baja California S to Costa Rica.
T. t. brachyptera Brewster, 1902 - NW Mexico (C & S Baja California, S Sonora).

Descriptive notes. 12-13 cm; 14-16 g. Male has forehead to nape matt green, nape with violet tinge, side of head, including area above and behind eye, white; back matt green, rump and uppertail-coverts violet-blue, extensive white on side of rump (can appear white-rumped); wings and tail black, tertials edged white when fresh, tail short and shallowly forked; underparts white, underwing-coverts pale grey. Differs from *T. bicolor* in having matt plumage, more extensive white on head side, white on rump side. Female is duller, with browner head. Juvenile is browner. Race *brachyptera* is smaller than nominate, has less of a violet sheen on scapulars and back, rump variable. Voice. Twitter call is used in territorial and courtship contexts; other calls include a contact call "chee-chee" and an alarm call.

Habitat. Open deciduous, coniferous and mixed woodland; also other open areas, such as cliffs, deserts or prairies, if suitable nesting sites available. Usually at 2000-3500 m in S, at lower elevations and coastal in N; breeds at up to 4000 m, but commonest at 1500-3000 m. Often near water on migration. On wintering grounds typically in low-elevation habitats such as valleys, coastal plains and intertidal flats, but also over plains and forest in mountainous areas to 3000 m, occasionally to 3700 m.

Food and Feeding. Insects. In samples taken throughout North America, diet consisted of 36% Hemiptera (leafhoppers, leafbugs), 29% flies (Diptera), 23% hymenopterans (mostly ants, some wasps and bees), 11% beetles (Coleoptera); moths (Lepidoptera) and mayflies (Ephemeroptera) also recorded. Forages in small groups or loose flocks, both low over ground or water and high up, often higher than other hirundines. Sometimes in flocks with other swallows and swifts (Apodidae). Flight a mix of fast flapping and gliding, wingbeats more rapid than those of *T. bicolor*. Has been recorded as feeding on the ground.

Breeding. Mainly May-Aug, from Feb in Mexico; single-brooded. Solitary, or in groups of typically up to 25 pairs, occasionally more than 50 pairs; nests in Colorado were at least 1 km apart. Male guards female during nest-building and egg-laying. Nest made of grass, rootlets, straw and twiglets, with feather lining, built mainly by female, work takes from a few days to a few weeks; placed in hole in tree, cliff or, occasionally, bank or wall or in other swallow nest, or nestbox used; in hole in cactus in NW Mexico (*brachyptera*). Clutch 2-7 eggs, usually 4-6; incubation by female, period 14-15 days; hatching over more than 1 day, up to 5 days, chicks fed by both parents, female more than male, intervals between feeds a few minutes (in one case, range 20 seconds to 4 minutes), fledging 23-24 days; young remain near nest and fed by parents for a few days.

Movements. Nominate race mainly a long-distance migrant, winters from S Sonora and the Mexican Plateau S to Honduras and El Salvador, occasionally to Costa Rica; resident in Mexico, and reported to occur in winter also in C & S California, and casually to C Arizona and W Panama. Forms flocks before and during migration. Main autumn passage early Aug to late Oct; return migration mid-Mar to early May, males arriving before females; often returns to same site in successive years, e.g. in Colorado 84% of females returned to breeding site, 44% to previous year's nest-site. Race *brachyptera* moves from mountains to lower elevations in Mexico. Vagrant to Aleutian Is, also to E of range in e.g. Manitoba, Ontario, Ohio, New Jersey, C Texas, Yucatán, and in S to N Colombia; also several sight reports E to Nova Scotia and New Hampshire.

Status and Conservation. Not globally threatened. Total population estimated at c. 11,000,000 birds. Generally fairly common to common, especially in mountain ranges around Los Angeles (California). Population has increased in N Plains States, but decreased locally in Mexico. May have benefited from provision of nest-sites by humans, but suffers competition for nest-sites with introduced Common Starling (*Sturnus vulgaris*) and House Sparrow (*Passer domesticus*); has probably lost natural sites through deforestation.

Bibliography. Anon. 19. Golden Swallow

Tachycineta euchrysea

French: Hirondelle dorée **German**: Antillenschwalbe **Spanish**: Golondrina Dorada

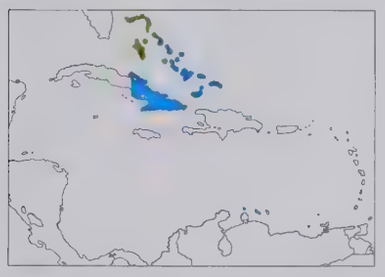
Taxonomy. *Hirundo euchrysea* Gosse, 1847, Jamaica.
Has sometimes been placed in a separate genus *Lamprochelidon* or *Kalochelidon*. DNA studies, however, indicate close relationship with *T. thalassina* and *T. cyaneoviridis*. Two subspecies recognized.

Subspecies and Distribution.
T. e. euchrysea (Gosse, 1847) - Jamaica.
T. e. sclateri (Cory, 1884) - Hispaniola (Haiti and Dominican Republic).

Descriptive notes. 12 cm. Male is strongly iridescent bronzy green to coppery bronze above, upperparts often appearing golden; wings and tail dusky bronze-green, tail slightly forked; underparts white, underwing-coverts dusky with bronze-green margins. Female is similar but duller, with some grey-brown mottling on breast. Juvenile is duller and browner, with extensive grey-brown mottling on breast. Race *sclateri* is less golden, has longer wings, smaller bill, deeper tail fork. Voice. A "tchee-weet" call has been recorded.

Habitat. Montane humid forest and pine (*Pinus*) forest at up to 2000 m, also secondary forest. Forages also over open country, cultivation.

Food and Feeding. Diet includes beetles (Coleoptera) and parasitic wasps (Hymenoptera). Feeds alone or in small groups, often low over the ground.



Breeding. Jun-Jul in Jamaica; also Apr in Haiti. Often colonial. Nest made of vegetable fibres, lined with fibres and feathers, placed in cavity, such as old woodpecker (Picidae) hole, in dead pine tree, or in cave, among boulders in old mine, or in eaves of building. Clutch 3 eggs.
Movements. Resident; may move to lower altitudes after breeding.
Status and Conservation. VULNERABLE. Restricted-range species: present in Jamaica EBA and Hispaniola EBA. Total population estimated at 2500-10,000 individuals within small and fragmented range of 8200 km²; both numbers and range decreasing. Legally protected in Jamaica, where nominate race was common in 19th century; now very rare and local, occurring in Cockpit Country and across C highlands to Blue Mts and environs; few recent records. Race *sclateri* is locally common, particularly in Cordillera Central, Sierra de Baoruco and Massif de la Selle, but has also declined. Clearance of forest for agriculture has severely reduced suitable habitat on Hispaniola; loss of nest-sites may also be responsible for decline on Jamaica. Occurs in several protected areas where some habitat survives, as in La Visite and Macaya National Parks, in Haiti, and Cockpit Country and the Blue and John Crow Mts, in Jamaica; the Jamaican reserves, however, are not managed. Six montane-forest areas in Dominican Republic have been proposed as protected areas. Target conservation measures are to identify breeding sites, officially to designate proposed protected areas, to consider a nestbox scheme, and to prepare management plans for main reserves.
Bibliography. Bangs & Kennard (1920), Bond (1928a, 1943, 1961a, 1985), Dod (1987, 1992), Downer (1982), Faaborg (1985), Fernández & Keith (2003), Hellmayr (1935), Keith *et al.* (2003), King (1978/79), March (1863), Osburn (1858, 1869), Raffaele *et al.* (1998, 2003), Ridgway (1904), Sheldon (1998), Stattersfield & Capper (2000), Stotz *et al.* (1996), Sutton (1973), Wetmore & Lincoln (1933), Wetmore & Swales (1931), Woods & Ottenwalder (1986).

20. Bahama Swallow

Tachycineta cyaneoviridis

French: Hirondelle des Bahamas **Spanish**: Golondrina de las Bahamas
German: Bahamaschwalbe

Taxonomy. *Hirundo cyaneoviridis* H. Bryant, 1859, New Providence, Bahama Islands.
Has sometimes been placed in a separate genus *Callichelidon*. DNA studies, however, indicate close relationship with *T. thalassina* and *T. euchrysea*. Monotypic.
Distribution. N Bahamas (islands of Grand Bahama, Great Abaco and Andros, possibly also New Providence); in non-breeding season S to E Cuba.

Descriptive notes. 15 cm; 16·3-19·5 g. Male has forehead to back green, rump bluish-green; wings and tail blue, tail strongly forked; underparts and underwing-coverts white. Differs from *T. bicolor* in blue, rather than black, wings, deeply forked tail. Female is duller than male, underparts less pure white, tail shorter. Juvenile is duller and browner, with shorter tail. Voice. A metallic "chep" or "chi-chep" call has been recorded.
Habitat. Caribbean pine (*Pinus caribaea*) forest; also around human habitations. Forages in open areas, such as woodland clearings, fields, marshes and coastal areas.
Food and Feeding. Diet includes flies (Diptera) and beetles (Coleoptera). Feeds both low over ground and high up, often gliding. Forms small flocks.
Breeding. Late Apr-Jul; usually single brood but, of 12 nests, at least one and possibly three were second broods. Solitary or in groups; nests in pines c. 150 m apart. Nest made of pine needles, *Casuarina* twigs, and grass, lining typically of pine bark and feathers, but dry leaves, shed lizard skin, flower petals, a butterfly wing, turtle grass, paper, shredded plastic and paint chips also recorded; typically in old woodpecker (Picidae) hole in dead Caribbean pine tree, also in other cavity in tree, at average height of 8·8 m (range 6-11·4 m), sometimes in artificial cavity in various sites, including street light, pipe, wall, electrical conduit box, rooftop ventilation unit, nestbox and artificial gourd, nest larger in artificial sites. Clutch 2-4 eggs, usually 3; incubation probably by female only, period 15-17 days; hatching over 1-2 days, chicks fed by both parents, fledging 22-25 days. Hatching success 87%, fledging success 81%.
Movements. After breeding, spreads throughout Bahamas and S to E Cuba, some irregularly W to S Florida, Florida Keys and Dry Tortugas. A few appear to remain on breeding grounds.
Status and Conservation. VULNERABLE. Restricted-range species: present in Bahamas EBA. Population estimated at 4800 individuals; decreasing. Range small and fragmented. Breeding population on New Providence possibly extinct or, at least, very small. Pine forest limited in extent, and was logged extensively in 1950s. Further logging and proposed housing developments would reduce available habitat. Areas of forest also destroyed by hurricanes. Some competition for nest-sites with introduced Common Starlings (*Sturnus vulgaris*) and House Sparrows (*Passer domesticus*). In 1995, a nestbox scheme was started on Grand Bahama in order to provide extra sites, but only three of 227 boxes were occupied. Target conservation measures are assessment of species' status and that of its breeding habitat, determination of its precise non-breeding distribution and habitat requirements, implementation of a programme to manage its main nest-sites (pine snags), and monitoring of use of nestboxes.
Bibliography. Allen (1996, 1997a, 1997b, 1998), Allen & Hitchcox (1997), Anon. 21. Tumbes Swallow

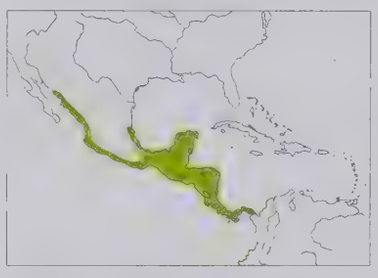
Tachycineta stolzmanni

French: Hirondelle de Stolzmann **Spanish**: Golondrina de Tumbes
German: Stolzmannschwalbe

Other common names: Chepen/Stolzmann's/West Peruvian Swallow

Taxonomy. *Hirundo Stolzmanni* R. A. Philippi [Krumwiede], 1902, Chepen, La Libertad, Peru.
Forms a superspecies with *T. albilinea* and *T. albiventer*; was for many years considered conspecific with former, but differs in nest structure, flight call and morphology, and recent cytochrome *b* data also support treatment as separate species. Monotypic.
Distribution. Coast of SW Ecuador (Loja) and NW Peru (S to La Libertad).



Descriptive notes. 13 cm; 11-12 g. Has glossy blue-green forehead to back, sometimes very thin pale supraloral streak (often absent); rump white, dusky shaft streaks on uppertail-coverts; wings and tail black, tail shallowly forked; underparts white with grey wash, especially on breast, dusky shaft streaks; underwing-coverts smoky grey. Distinguished from very similar *T. albilinea* by lack of (or indistinct) white line above lores, greyer underparts with more pronounced shaft streaks, especially on throat, longer tail. Sexes alike. Juvenile is brown above, has less pronounced streaking below. Voice. A buzzy "dzeet" call has been recorded.
Habitat. Open, low-lying country: semi-arid areas with acacia (*Acacia*) or mesquite (*Prosopis*) trees, mesquite groves, irrigated farmland, and coastal lagoons.
Food and Feeding. No information; probably similar to that of *T. albilinea*.
Breeding. Nest-building recorded in Apr, after start of rains. Solitary. One nest found, almost 2 m above ground in a tree hole, possibly made by a piculet or woodpecker (Picidae), hole led into a crevice, on floor of which were small white pebbles; laying had not yet started.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Locally common to fairly common, but with small range. A poorly known species.
Bibliography. Best *et al.* (1997), Clements & Shany (2001), Hellmayr (1935), Parker *et al.* (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1989), Ridgely *et al.* (1998), Robbins *et al.* (1997), Schulenberg & Parker (1981), Walker (2002), Zimmer (1955a).

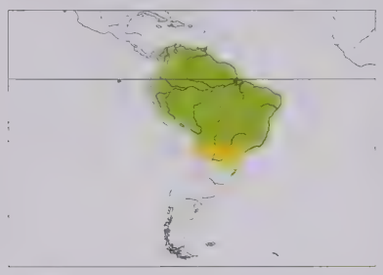
22. Mangrove Swallow

Tachycineta albilinea

French: Hirondelle des mangroves **Spanish**: Golondrina de Manglar
German: Mangroveschwalbe

Taxonomy. *Petrochelidon albilinea* Lawrence, 1863, New Granada = line of Panama Railroad, Panama.
This species (and, by extension, *T. stolzmanni*), along with *T. bicolor*, *T. albiventer*, *T. leucorrhoa* and *T. meyeni*, sometimes placed in separate genus *Iridoprocne*, but DNA studies indicate close relationship of these taxa with clade consisting of *T. thalassina*, *T. euchrysea* and *T. cyaneoviridis*, and support placement of all in a single genus. Forms a superspecies with *T. stolzmanni* and *T. albiventer*. Birds from NW Mexico (Sonora) sometimes separated as race *rhizophorae*, but variation not constant. Monotypic.
Distribution. W & E Mexico (S from C Sonora, SE San Luis Potosí and S Tamaulipas) S to Panama (E to E Colón and E Darién).

Descriptive notes. 11-12 cm; 10-16 g. Has white line above lores, glossy blue-green crown to back, white rump, browner tail-coverts; wings black, white tips of tertials, inner secondaries and inner greater wing-coverts in fresh plumage; tail black, shallowly forked; underparts white, sometimes faint dark shaft streaks; underwing-coverts white. Distinguished from very similar *T. stolzmanni* by distinct white line above lores, whiter underparts with fainter streaks, shorter tail. Sexes alike. Juvenile has grey-brown upperparts, grey-brown wash on underparts. Voice. Song is a soft trilling; also chirping calls "chirichrit", "chrit", "chriet" and an alarm call.
Habitat. Often found along coastal beaches and in mangroves; also inland over lowland waterbodies, such as rivers, lakes and marshes, as well as wet meadows. Typically forages over water.
Food and Feeding. Two adult stomachs contained Hymenoptera (mainly flying ants), beetles (Coleoptera), bugs (Hemiptera) and flies (Diptera). Nestling diet in Panama 26% Odonata, 26% Lepidoptera, 21% sarcophagid Diptera, 15% bees (Apidae), and a few other hymenopterans (mainly flying ants) and dipterans. Feeds alone or in pairs, typically low over water, but also up to 30 m or more. Flight direct, rapid wingbeats with some gliding. One pair had foraging area of c. 500 m². Hunts close to nest when collecting food for nestlings, sometimes over 200 m from nest when feeding self. Forages mostly in early morning and late afternoon.
Breeding. Mar/Apr-Jun/Jul in Mexico and N Central America, Jan-Jul in Panama, laying not synchronous within a population; two broods reported. Socially monogamous; moderate level of extra-pair paternity (15% of nestlings, 26% of broods). Solitary, nests 50-1300 m apart (average 313 m), and highly territorial, aggressive to intruders. Nest made of dry grass, stems, moss and leaves, lined with feathers, placed in hole in tree stump or dead tree, often partially submerged one; old woodpecker (Picidae) holes used, also other birds' nests, e.g. recorded building inside domed nest of Rusty-margined (*Myiozetetes cayanensis*) and Social Flycatchers (*M. similis*), also crevice in rocks, and occasionally artificial structure such as wall and the pilings of a wharf; nestboxes used; recorded as building near wasp nests. Clutch 3-5 eggs; incubation 17 days; hatching asynchronous, chicks fed by both sexes, average 17 times per hour, mainly early morning and late afternoon; fledging 23-27 days. In one study, nests lost to termites (Isoptera), predators and competition from *Progne chalybea*.
Movements. Apparently mainly resident; forms small flocks after breeding, sometimes hundreds near roosts. Probably some post-breeding movements, as numbers can fluctuate seasonally; in Mexico, numbers in Sonora decrease mid-summer to mid-Mar and numbers in Nayarit increase over winter.
Status and Conservation. Not globally threatened. Generally common or fairly common; rarer inland than on coast. Numbers thought to have declined in some areas, such as El Salvador, perhaps because of habitat loss or pesticide use.



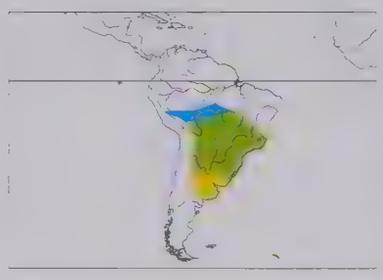
Bibliography. Anon. (1998a), Binford (1989), Blake, E.R. (1953), Blake, E.R. & Hanson (1942), Brodkorb (1943), Dyrcz (1984, 2000a), Friedmann *et al.* (1950), Griscom (1926), Hellmayr (1935), Howell & Webb (1995a), Komar & Domínguez (2001), Land (1970), Lee Jones (2004), Lowery & Dalquest (1951), Monroe (1968), Moore *et al.* (1999), Paynter (1955), Phillips (1986), Ricklefs (1971), Ridgely & Gwynne (1989), Ridgway (1904), Russell (1964), Russell & Lamm (1978), Schaldach (1963), Slud (1960, 1964, 1980), Stiles & Skutch (1989), Stotz *et al.* (1996), Thurber *et al.* (1987), Traylor (1941), Wendelken & Martin (1986), Wetmore (1943, 1957), Wetmore *et al.* (1984), Whitacre & Thorstrom (1992), Willis & Eisenmann (1979).

23. White-winged Swallow

Tachycineta albiventer

French: Hirondelle à ailes blanches **German**: Cayenneschwalbe **Spanish**: Golondrina Aliblanca

Taxonomy. *Hirundo albiventer* Boddaert, 1783, Cayenne.
This species, along with *T. bicolor*, *T. albilinea* (and, by extension, *T. stolzmanni*), *T. leucorrhoa* and *T. meyeni*, sometimes placed in separate genus *Iridoprocne*, but DNA studies indicate close relationship of these taxa with clade consisting of *T. thalassina*, *T. euchrysea* and *T. cyaneoviridis*, and support placement of all in a single genus. Forms a superspecies with *T. stolzmanni* and *T. albilinea*. Monotypic.
Distribution. N & C South America (except Pacific coast), from Colombia, Venezuela, Trinidad and the Guianas S to N Argentina, Paraguay and SE Brazil.



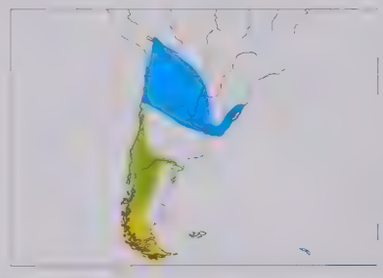
Descriptive notes. 14 cm; 14-17 g. Male has forehead to back glossy blue-green, rump white; wings black, large white wing patch formed by white edges of greater wing-coverts, tertials and secondaries; tail black, shallowly forked; underparts and underwing-coverts white. Differs from *T. albilinea* in having more white on wing, no white line above lores. Female is like male, but with less white on wing. Juvenile is browner, with less white on wing, greyer underparts. Voice. Song is a soft gurgling; also a "wrreeeet" and an alarm call.
Habitat. Open, lowland areas near water, such as mangroves, coastal beaches, rivers, lakes, reservoirs, flooded *llanos*, savanna, to 500 m. Also forages over pastures, grassy airstrips and sewage ponds.
Food and Feeding. Diet includes flies (Diptera), Hymenoptera, beetles (Coleoptera), Lepidoptera. Feeds alone, sometimes in small groups, low over water or ground; flight fast and direct. Often with *Atticora fasciata*, but keeps to the more open stretches of water.
Breeding. Apr-Aug in Trinidad, Feb-Apr in Venezuela; Sept-Apr in S. Solitary, and aggressive to intruders; sometimes in loose groups if suitable nest-sites clumped. Nest made of dry grass and rootlets, lined with feathers, usually a few metres above water in hole or crevice in cliff, rocks, tree stump, pipe, or house eaves; recorded as nesting on ferry boats in active use. Clutch 3-6 eggs, usually 4 or 5; no information on incubation and fledging periods.
Movements. Resident in N; in S a breeding visitor mid-Sept to mid-Apr, probably migrating to N of range. Vagrant in Panama.
Status and Conservation. Not globally threatened. Generally common and widespread throughout range.
Bibliography. Belton (1985), Burtt *et al.* (1988), Canevari *et al.* (1991), Chapman (1917a, 1917b), Chebez *et al.* (1999), Cherrie (1916), Contreras (1995a), Davies *et al.* (1994), ffrench (1991), Fraga & Narosky (1985), Gochfeld *et al.* (1980), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Hellmayr (1935), Hilty (2003), Hilty & Brown (1986), Parker & Goerck (1997), de la Peña (1987, 1989), Pereyra (1969), Perry *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1989), Riveros (1989), Robinson (1997), do Rosário (1996), Schmitt *et al.* (1986), Seutin (1998), Short (1975), Sick (1993), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tostain (1979), Tostain *et al.* (1992), Zimmer, J.T. (1955a), Zimmer, K.J. & Hilty (1997), Zimmer, K.J. *et al.* (1997).

24. White-rumped Swallow

Tachycineta leucorrhoa

French: Hirondelle à diadème **German**: Weißbürzelschwalbe **Spanish**: Golondrina Cejiblanca

Taxonomy. *Hirundo leucorrhoa* Vieillot, 1817, Paraguay.
This species, along with *T. bicolor*, *T. albilinea* (and, by extension, *T. stolzmanni*), *T. albiventer* and *T. meyeni*, sometimes placed in separate genus *Iridoprocne*, but DNA studies indicate close relationship of these taxa with clade consisting of *T. thalassina*, *T. euchrysea* and *T. cyaneoviridis*, and support placement of all in a single genus. Forms a superspecies with *T. meyeni*; formerly considered conspecific owing to similarities in morphology and voice, but comparison of DNA sequences supports treatment as separate species. Monotypic.
Distribution. Breeds from C & E Bolivia and C Brazil (S from C Mato Grosso, C Goiás and Espírito Santo) S to N Argentina (S to La Pampa and Buenos Aires) and Uruguay; in non-breeding season occurs N to SE Peru, N Bolivia and NC Brazil.
Descriptive notes. 13 cm; 17-21 g. Has white streak above lores, often extending over bill; crown and upperparts glossy blue (more greenish-blue when not breeding), rump white; wings black, white tips of inner secondaries, tertials and greater wing-coverts (fade with age); tail black, shallowly forked; underparts and underwing-coverts white. Distinguished from similar *T. meyeni* by white above lores. Sexes alike. Juvenile is duller and browner, with dusky breast. Voice. Song is a soft gurgling; also an alarm call.



Habitat. Open and semi-open country near water, such as lagoons and marshes, woodland edge, and human habitations. Lowlands to 1000 m. Forages over water and grassland and in open woodland.
Food and Feeding. Diet includes flies (Diptera), beetles (Coleoptera), flying ants (Hymenoptera), Orthoptera and Lepidoptera. Feeds alone or in small groups, often low over water or ground; flight fast and direct. Follows humans and other animals.
Breeding. Oct-Dec in Brazil, Oct-Feb in Argentina. Solitary, and aggressive to intruders. Nest made of plant fibres, lined with hair and feathers, placed in hole or crevice in tree or dead snag, in abandoned nest of e.g. hornero (*Furnarius*) or Firewood-gatherer (*Anumbius annumbi*), hole in fence post, or in eaves, roof, thatch or pipe; often uses isolated buildings, less often buildings in towns. Clutch 4-7 eggs; incubation period 15-16 days, fledging period 21-25 days.
Movements. Migratory in S, mostly absent from Argentina and Uruguay May-Aug. Occurs all year in Brazil, but few in non-breeding season in SE. Forms flocks after breeding, sometimes of hundreds of individuals. Non-breeders occur N to SE Peru (N to Junín), N Bolivia and NC Brazil (N Mato Grasso).
Status and Conservation. Not globally threatened. Generally common or fairly common. May benefit from using artificial nest-sites, but does not often breed in towns.
Bibliography. Alabarce & Periss (1991), Aravena (1928), Belton (1985), Brooks *et al.* (1993), Canevari *et al.* (1991), Capper *et al.* (2000), Chebez *et al.* (1999), Contreras (1995a), Daguerre (1922), Fraga & Narosky (1985), Hayes (1995), Hellmayr (1935), Klimaitis & Moschione (1987), Marelli (1919), de la Peña (1987, 1989, 1996), Pereyra (1969), Ridgely & Tudor (1989), Riveros (1989), do Rosário (1996), Rothstein (1992), Sclater & Hudson (1888), Scott & Brooke (1985), Short (1975), Sick (1993), Stotz *et al.* (1996), Wetmore (1926), Zotta (1936).

25. Chilean Swallow

Tachycineta meyeni

French: Hirondelle du Chili **German**: Chileschwalbe **Spanish**: Golondrina Chilena

Taxonomy. *Petrochelidon Meyeni* Cabanis, 1850, Santiago, Chile.
Originally described as *Hirundo leucopyga* (and specific epithet often still used), but that name invalid as preoccupied. This species, along with *T. bicolor*, *T. albilinea* (and, by extension, *T. stolzmanni*), *T. albiventer* and *T. leucorrhoa*, sometimes placed in separate genus *Iridoprocne*, but DNA studies indicate close relationship of these taxa with clade consisting of *T. thalassina*, *T. euchrysea* and *T. cyaneoviridis*, and support placement of all in a single genus. Forms a superspecies with *T. leucorrhoa*; formerly considered conspecific owing to similarities in morphology and voice, but comparison of DNA sequences supports treatment as separate species. Monotypic.
Distribution. Breeds from C Chile (S from Atacama) and SW Argentina (S from Neuquén and W Río Negro) S to Tierra del Fuego; migrates N as far as C Bolivia, Paraguay and SE Brazil (Rio Grande do Sul).

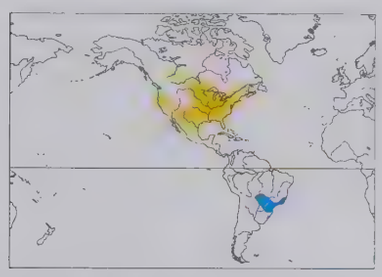
Descriptive notes. 12 cm; 15-20 g. Has forehead and face to upperparts deep blue, white rump; wings black, white tips of tertials and inner secondaries (abrade with age); tail black, slightly forked; underparts white, underwing-coverts pale grey-brown. Differs from similar *T. leucorrhoa* in lack of white supraloral streak, bluer plumage without green sheen. Sexes alike. Juvenile is duller and browner. Voice. Song is a gurgling, ending with lower-pitched guttural phrases.
Habitat. Open and semi-open country near water, such as marshes, lakes, rivers, lagoons, coastal areas, also open woodland, clearings and forest edge, scrub and human habitations, including towns.
Food and Feeding. Diet known to include flies (Diptera), beetles (Coleoptera), Hymenoptera (flying ants) and heteropteran bugs. Also recorded ingesting charred animal bones, presumably for calcium. Feeds alone or in small groups, low over ground; flight fast and direct.
Breeding. Sept-Feb in Chile, where sometimes 2-3 broods; Oct-Feb in Tierra del Fuego. Solitary, or in loose groups if suitable nest-sites clumped. Nest made of dry grass, lined with feathers, placed in tree cavity, such as old hole of woodpecker (Picidae), or in house eaves or hole in wall. Clutch 3-6 eggs; no information on incubation and fledging periods.
Movements. Resident in N. Migratory in S, moving N & E to spend non-breeding season mainly in Bolivia and Paraguay S to N Argentina and SE Brazil; possibly also S Peru. Regular passage visitor to Falklands, where bred in 1983/84. Forms flocks after breeding, sometimes with other hirundines.
Status and Conservation. Not globally threatened. Considered to be generally common or fairly common; the most abundant hirundine in Chile. Probably benefits from its frequent use of buildings as nest-sites.
Bibliography. Adams & Templeton (1979), Belton (1985), Canevari *et al.* (1991), Chebez & Bertonatti (1994), Chebez *et al.* (1999), Couve & Vidal-Ojeda (2003), Fjeldså & Krabbe (1990), Fraga & Narosky (1985), Friedmann (1927), Harris (1998), Hayes (1995), Humphrey *et al.* (1970), Jaramillo (2003), Johnson (1967), Klimaitis & Moschione (1987), Maccormick (2004), Meyer de Schauensee (1966, 1982), de la Peña (1987, 1989), Ridgely & Tudor (1989), Schmitt *et al.* (1986), Schulenberg & Remsen (1982), Stotz *et al.* (1996), Vuilleumier (1985), Woods & Woods (1997), Zotta (1936, 1940).

PLATE 65 ➤

PLATE 65

inches 3

cm 8



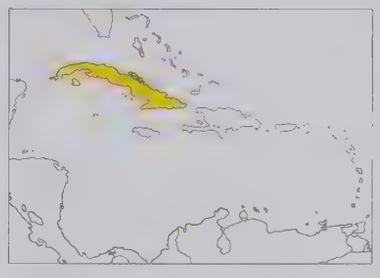
Genus *PROGNE* Boie, 1826

26. **Purple Martin**

Progne subis

French: Hirondelle noire **German**: Purpurschwalbe **Spanish**: Golondrina Purpúrea

Taxonomy. *Hirundo subis* Linnaeus, 1758, Hudson Bay, Canada.
Forms a superspecies with all congeners except *P. tapera*. Sometimes considered conspecific with *P. cryptoleuca*, *P. dominicensis* and *P. sinaloae*. Taxonomy uncertain, and subspecific status of birds in N Rockies, on Pacific coast, and in SW USA and Mexico unclear. Birds from S Arizona described as race *oberholseri*, usually considered synonymous with *hesperia*. Three subspecies generally recognized.
Subspecies and Distribution.
P. s. arboricola Behle, 1968 - mountains of W North America (probably including Pacific Northwest) E to Rocky Mts and S to NW & N Mexico (including N Baja California); winters probably in South America.
P. s. subis (Linnaeus, 1758) - E of Rocky Mts, from S Canada (C Alberta and C Saskatchewan E to SW & S Ontario, S Quebec, E New Brunswick and NW Nova Scotia) S to S USA (E from C Plains States, W Kansas and C & SW Texas) and C Mexican Highlands; winters in South America E of Andes.
P. s. hesperia Brewster, 1889 - SW USA (S Arizona lowlands) and NW Mexico (S Baja California, and lowlands S to SC Sonora, possibly along coast to N Sinaloa and on Gulf of California islands); probably winters in South America.



Descriptive notes. 19 cm; 48-64 g. Male is glossy steel-blue to bluish-black; concealed tufts of white feathers on side; wings and tail sooty-black, tail moderately forked. Distinguished from extremely similar *P. elegans* with difficulty, but tail slightly shorter and less deeply forked. Female nominate race is much duller, forehead and hindneck grey, throat dusky grey with fine streaks, upper breast and sides dusky brown with greyish-white feather edges, rest of underparts greyish-white with dusky streaks. Juvenile has grey-brown upperparts and throat, rest of underparts grey-white; first-year male resembles adult female but some blue feathers on head and underparts, also wing and tail shorter than adult male's; first-year female paler below and more brown above than adult. Races differ in size and in plumage of female: *arboricola* is largest, female with whitish forehead and hindcollar, much paler below than nominate; *hesperia* is smallest, plumage as previous. Voice. During courtship, males sing gurgling "croak" song, females "chortle" song; also, a "dawn song", similar to "croak" song but without terminal gratings, is sung before daylight and may attract conspecifics; other calls include "cher" and "chortle" calls used in a variety of contexts, "zwrack" and "zweet" alarm calls, a territorial "hee-hee" call, and a "choo" call used by females to lead fledged broods; call structure varies between western montane and eastern populations.
Habitat. Natural habitat is forest edge and semi-open areas with dead snags, especially near water such as ponds or marshes. Race *hesperia* inhabits saguaro (*Carnegiea gigantea*) desert; other W populations also occur in open pine (*Pinus*) forest and pine-oak (*Quercus*) forest. In E, now associated almost exclusively with human habitations, including towns and cities. Mostly up to 2600 m. Forages over open areas, such as fields, cultivation, water, marshes. Roosts in trees, and on bridges and buildings, often in towns in winter quarters.
Food and Feeding. In samples taken throughout North America, diet consisted of 23% Hymenoptera (mainly ants and wasps, a few bees), 16% flies (Diptera), 15% dragonflies and damselfies (Odonata), 15% bugs (Hemiptera), 13% beetles (Coleoptera), 9% moths and butterflies (Lepidoptera), 1% grasshoppers and crickets (Orthoptera); other prey taken include caddis flies (Trichoptera), mayflies (Ephemeroptera), termites (Isoptera) and spiders (Araneae). Known to take large cicadas (Cicadidae) and monarch butterflies (*Danaus plexippus*). In Kansas, commonest prey were beetles, aphids (Homoptera), hemipteran bugs, parasitic Hymenoptera, and craneflies (Tipulidae); more dipterans and homopterans taken early in breeding season, and hemipterans, lepidopterans and hymenopterans late in season. In Alberta, commonest prey were Odonata, syrphid flies and midges, nymphalid butterflies, hymenopterans and coleopterans. Feeds alone or in pairs, high up, to c. 50 m, sometimes 150 m. Often flies in circles, alternating flapping with gliding. Occasionally takes prey from vegetation, ground or water.
Breeding. Start of egg-laying varies, from late Mar in Florida to mid-Jun in Canada; single-brooded (rarely, two broods in S USA). Socially monogamous, with occasional polygyny (less than 5%); extra-pair paternity occurs, and related to age (in one study, up to 43% of chicks in nests of first-year males were extra-pair, only 4% in nests of older males). Solitary or in groups, depending on nest-site availability, groups mostly fewer than 35 pairs but 300 or more reported; aggressive to intruders, pair nesting in cactus defends area of 20-30 m radius around nest, and in E male defends more than one compartment in artificial "martin house". Male advertises nest-site to female with "Claiming-Reclaiming display"; extent of mate-guarding by male variable. Nest made of twigs, stems and leaves, including fresh green leaves, with variable amounts of mud forming wall next to entrance hole, most of material collected by female, but male often adds green leaves; placed in old woodpecker (Picidae) hole in dead tree or cactus, in crevice in rocks or cliff, or cavity in building, streetlamp or other artificial structures, also in artificial gourd or birdhouse (especially in E of range); sites reused in subsequent years. Clutch 4-5 eggs, usually 3-6 (rarely 2 or up to 8), smaller clutches laid by first-year females; intraspecific brood parasitism occasionally recorded (in three studies, respectively 0%, 3-6% of nesting attempts, up to 36% of young reared by first-years); incubation by female (but male will sit in her absence), attentive periods usually 4-15 minutes, incubation period 15-18 days; chicks fed by both sexes, c. 13 times per brood per hour, fledging 27-36 days, generally 28-29 days; young fed for further 5-7 days, return to nest to roost for 1-12 days. Breeding success can be poor in cold, wet weather, also affected by ectoparasites, also adult mortality sometimes high in adverse weather (e.g. cold snaps and prolonged rain); fledging success c. 50-85% of eggs laid; nest-sites usurped and nest contents destroyed by House Sparrows (*Passer domesticus*) and Common Starlings (*Sturnus vulgaris*). Recorded longevity 13 years 9 months.
Movements. Migratory; forms large post-breeding flocks, some of hundreds of thousands of birds. E population (nominate race) is a long-distance migrant to South America, where wintering area not well known but appears to be mainly E Bolivia and S & SE Brazil (S from S Mato Grosso, São Paulo, Rio de Janeiro and Espírito Santo); winter ranges of W races (*arboricola*, *hesperia*) unknown, probably also in South America; recently recorded in coastal Peru. Migrates through Mexico, Central America and N South America, but many of E population possibly fly across Gulf of Mexico. Peak autumn migration late Jul-Sept, most reaching Amazonia by mid-Nov. Returns early to breeding grounds, first arrivals from mid-Jan in Florida to early May in Canada; older males arrive first, to acquire best nest-cavities. Vagrant in e.g. Pribilof Is, Alaska, Yukon, Ontario, Prince Edward I, Newfoundland, in Pacific Ocean off Central America (Clipperton Atoll, Cocos I), in W & S Atlantic (e.g. Bermuda, Falkland Is), and in Europe (British Is).
Status and Conservation. Not globally threatened. Overall population estimated at c. 11,000,000 birds. Range has contracted in N, and population declining in N and also along Gulf coast and in S California; declines most evident since 1980. Recent increase noted along Atlantic coast, and possibly some range extension W in Great Plains, as a result of provision of martin houses; E population almost totally dependent on birdhouses. Competition from introduced House Sparrows and Common Starlings, together with clearance of dead trees in some areas, may be cause of decline since 19th century. Susceptible to periods of cold and wet weather, when large numbers, even entire populations, sometimes die; such mortality occurs regularly in N of range. In wintering range, human interference with roosts and use of pesticides may reduce numbers; large migratory roost-sites have been destroyed, or the birds harassed into leaving. Suggested conservation measures are provision and management of nestboxes and birdhouses in order to increase breeding numbers and breeding success, and protection of winter/migratory roosts.

27. **Cuban Martin**

Progne cryptoleuca

French: Hirondelle de Cuba **German**: Kubaschwalbe **Spanish**: Golondrina Cubana

Taxonomy. *Progne cryptoleuca* S. F. Baird, 1865, Cuba.
Forms a superspecies with all other members of genus except *P. tapera*. Has been variously considered a race of *P. subis* or of *P. dominicensis*; sometimes merged with latter and *P. sinaloae* as a single species. Monotypic.
Distribution. Breeds Cuba (including Cayo Romano) and I of Pines; non-breeding range unknown, probably in South America.

Descriptive notes. 18-19 cm. Male is glossy steel-blue, with concealed white band on lower abdomen; wings and tail sooty-black, tail forked. Differs from extremely similar *P. subis* in longer and more deeply forked tail, concealed white abdominal band. Female is duller, more sooty-brown with blue feather margins above, greenish-blue gloss on wings and tail, sooty-grey from side of head to breast, sides and underwing-coverts, rest of underparts white, dark shafts on breast, sides and undertail-coverts; resembles female *P. chalybea*, but duskier throat, breast and sides, whiter abdomen. Juvenile is much duller: first-year male resembles adult female, but often some blue feathers below. Voice. Song is a gurgling, including a high-pitched "twick-twick"; also a strong melodious warble.
Habitat. Semi-open areas, especially near water and along coast, such as scrub, farmland, mangroves; also human habitations.
Food and Feeding. Diet includes beetles (Coleoptera), heteropteran bugs, and Odonata. Flight alternately flapping and gliding.
Breeding. Apr-Aug. In loose colonies, sometimes solitary. Nest of vegetable fibres, e.g. grass, twigs and leaves, placed in natural tree hole or old hole of woodpecker (Picidae), cavity in rock, or artificial site such as pipe, or cavity in building. Clutch 3-5 eggs; incubation and fledging periods not documented.
Movements. Absent from breeding areas mid-Oct to Jan, most having left by Sept. Non-breeding range not known, presumably in South America; recorded as a migrant in Jamaica and Curaçao. Accidental in SE USA (S Florida).
Status and Conservation. Not globally threatened. Common throughout most of breeding range. Research required in order to establish whereabouts of non-breeding quarters.
Bibliography. Anon. (1998a), Arendt (1992), Balat & González (1982), Banks (2000), Barbour (1943), Bent (1942), Bond (1971), Bradley (2000), Chapman (1888), Danforth (1935b), Faaborg (1985), Garrido (1988), Garrido & Kirkconnell (2000), Gundlach (1873), Hellmayr (1935), Hill (2002), Kaufman (1996), Meyer de Schauensee (1966,

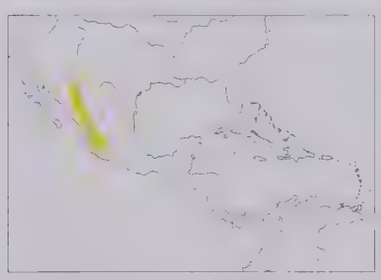
28. Caribbean Martin

Progne dominicensis

French: Hirondelle à ventre blanc **Spanish**: Golondrina Caribeña
German: Dominikanerschwalbe
Other common names: Snowy-bellied/White-bellied Martin

Taxonomy. *Hirundo dominicensis* J. F. Gmelin, 1789, Hispaniola.
Forms a superspecies with all congeners apart from *P. tapera*. Sometimes considered a race of *P. subis*; sometimes merged with *P. cryptoleuca* and *P. sinaloae* as a single species. Monotypic.
Distribution. Breeds Greater Antilles (except Cuba and I of Pines), Lesser Antilles and Tobago; non-breeding range uncertain, probably in South America.



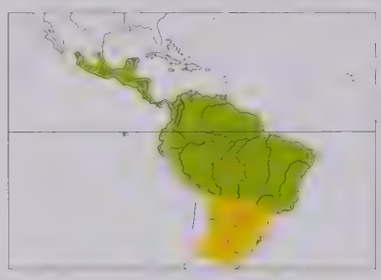
Descriptive notes. 18-19 cm; 38-42 g. Male is mostly glossy steel-blue; wings and tail black, tail moderately forked; lower breast, abdomen and undertail-coverts white, underwing-coverts with dark spots; underwing-coverts grey-brown. Distinguished from *P. sinaloae* by dark sides and flanks, creating narrower area of white on abdomen. Female is duller, more grey-brown, with pale on throat; differs from female *P. chalybea* in brown coloration extending more on to flanks, from *P. sinaloae* in more extensively pale throat, from *P. cryptoleuca* in darker upper breast. Juvenile is much duller than adult; first-year male resembles adult female, but faint blue gloss on upperparts. Voice. Song is a gurgling; calls include contact calls "zwoot" and "kweet", a "croot" uttered during courtship, a "wheet" used when a bird is alarmed, a "peak" alarm call and a "wrack" used during mobbing of predators.
Habitat. Semi-open areas, especially near water and along coast, such as second-growth scrub and farmland; also human habitations.
Food and Feeding. Twelve stomachs contained 33% Hymenoptera (mainly wasps), 24% pentatomid bugs, 26% flies (Diptera), 8% beetles (Coleoptera), 8% Odonata; five others contained pentatomid bugs, syrphid flies, Hymenoptera, beetles, hemipteran bugs and dragonflies. Also recorded as feeding on termites (Isoptera). Forages alone or in small groups, both high up and low over ground. Alternates gliding with flapping flight. Follows cattle.
Breeding. Generally Mar-Jul; single-brooded. Solitary or in loose groups, up to 30 pairs at one site. Nest of fibres, such as grass, twigs, leaves, paper and silk, placed in hole in cliff, cave, tree, chimney, pipe, belfry or building. Clutch 4-6 eggs, 2 on Tobago; no information on incubation and fledging periods.
Movements. Migratory, almost completely absent from West Indies Nov-Dec. Non-breeding range unknown, likely to be in South America. Regular summer breeder and passage migrant on Barbados, where generally uncommon in Oct, rarely seen in Nov, and recorded three times in Dec and twice in Jan; in 2000, however, 156 individuals located at roost on the island in Nov, and varying numbers throughout winter (29-45 in Dec, 15-22 in Jan, 30 in Feb, 40-80 in Mar), the first known occurrence of overwintering on any West Indian island. First records from Trinidad as recently as 1999 to 2001, all in spring (Feb-May), thus little evidence of regular passage through the island from farther N. Recorded also in Bahamas and Cayman Is, and on Cozumel I (off NE Yucatán Peninsula); several reports from Venezuela require confirmation.
Status and Conservation. Not globally threatened. Common and widespread in West Indies. Probably benefits from its frequent use of artificial nest-sites.
Bibliography. Anon. (1998a), Arendt (1992), Biaggi (1983), Blake, E.R. (1953), Bond (1928a, 1928b, 1943, 1971, 1985), Bradley (2000), Bryant (1867b), Buden (1987a), Burtt *et al.* (1988), Danforth (1929, 1935a), Davis & Miller (1962), Dobson (2002), Downer (1986, 1987), Faaborg (1985), ffrench (1991), Frost & Massiah (2001), Gochfeld (1965), Hellmayr (1935), Herklots (1961), Hill (2002), Keith (1997), Keith *et al.* (2003), Meyer de Schauensee (1966, 1982), Murphy & Hayes (2001), Phillips (1986), Pinchon (1976), Raffaele (1989), Raffaele *et al.* (1998), Ridgely & Tudor (1989), Ridgway (1904), Salmon (1975, 1991), Schönwetter (1979), Sheldon (1998), Stotz *et al.* (1996), Voous (1983), Wetmore (1916), Wetmore & Swales (1931).

29. Sinaloa Martin

Progne sinaloae

French: Hirondelle du Sinaloa **German**: Sinaloaschwalbe **Spanish**: Golondrina Sinaloense
Other common names: White-bellied Martin

Taxonomy. *Progne sinaloae* Nelson, 1898, Plomosas, Sinaloa, Mexico.
Forms a superspecies with others of genus apart from *P. tapera*. Variously considered to be a race of *P. subis* or of *P. dominicensis*; sometimes merged with latter and *P. cryptoleuca* as a single species. Has been known to hybridize with *P. chalybea*. Monotypic.
Distribution. Breeds W Mexico (NE Sonora S to Jalisco and Michoacán); non-breeding range uncertain, probably in South America.



Descriptive notes. 17-18 cm. Male is mostly glossy steel-blue; wings and tail blacker, tail forked; lower breast, abdomen and undertail-coverts white, indistinct dark shaft streaks on undertail-coverts. Differs from *P. chalybea* in greater contrast between dark and white areas below. Female is generally duller, upperparts sometimes mottled grey-brown, face, throat, breast and flanks dusky brown, pale median area of throat contrasting with darker breast, whitish abdomen and undertail-coverts. Juvenile undescribed; first-year male resembles adult female, but blue feathers on upperparts and some on breast. Voice. Calls not described; probably similar to those of congeners.
Habitat. Pine (*Pinus*) forest and mixed forest of pine and oak (*Quercus*), also semi-open woodland; to 2000 m. Possibly separated altitudinally from *P. subis* where the two overlap in range.
Food and Feeding. No information on diet; probably similar to that of congeners. Flight alternately gliding and flapping.
Breeding. Poorly known. Present on breeding grounds Mar-Aug. Seen in small groups. Nest in hole, probably mainly in trees. No information on clutch size and incubation and fledging periods.
Movements. Migratory. Migrants recorded on Pacific coast of Mexico and in Guatemala; non-breeding quarters unknown, probably in South America.
Status and Conservation. Not globally threatened. Data-deficient. Uncommon to fairly common, and local. Known from only nine sites on W slope of Sierra Madre Occidental, in states of Sonora, Jalisco and Michoacán. Of concern because of its small range and the fact that very little is known about its ecology and biology.
Bibliography. Anon. (1998a), Blake, E.R. (1953), Bond (1971), Ceballos & Valdelamar (2000), Davis & Miller (1962), Friedmann *et al.* (1957), Hellmayr (1935), Hill (2002), Holt (1926), Howell, S.N.G. & Webb (1995a), Howell, T.R. (1972), Lee Jones (2004), Phillips (1986), Ridgely & Gwynne (1989), Ridgway (1904), Stattersfield & Capper (2000), Stotz *et al.* (1996).

30. Grey-breasted Martin

Progne chalybea

French: Hirondelle chalybée **German**: Graubrustschwalbe **Spanish**: Golondrina Pechigrís
Other common names: White-bellied Martin

Taxonomy. *Hirundo chalybea* J. F. Gmelin, 1789, Cayenne.
Forms a superspecies with others of genus apart from *P. tapera*. Hybrids with *P. sinaloae* and *P. elegans* recorded. Race *warneri* often merged with nominate. Race *macrorhamphus* formerly known as *domestica*, but latter name invalid, as preoccupied. Three subspecies recognized.
Subspecies and Distribution.
P. c. warneri A. R. Phillips, 1986 - W Mexico (S from S Sinaloa).
P. c. chalybea (J. F. Gmelin, 1789) - E Mexico (from S Tamaulipas) S through Central America to Trinidad and N South America (S to NW Peru and, E of Andes, to N Bolivia, N Argentina and C & NE Brazil).
P. c. macrorhamphus Brooke, 1974 - C Bolivia and E Brazil S to N Argentina (S to Mendoza, Córdoba and Buenos Aires) and Uruguay; migrates to N South America.

Descriptive notes. 16-18 cm; 33-50 g. Male nominate race has forehead to crown and upperparts glossy steel-blue; wings and tail black, tail moderately forked; chin, throat, breast and sides grey-brown, breast occasionally blue-black, abdomen and undertail-coverts white with some fine dusky shaft streaks; underwing-coverts sooty-grey. Distinguished from *P. sinaloae* by less contrast between dark and white areas below. Female is duller, with mottled upperparts, paler throat; differs from female *P. subis* in whiter underparts, browner forehead, from female *P. dominicensis* in brown extending less on to flanks. Juvenile is much duller than male, paler throat and underparts less contrasting; first-year male resembles adult female. Race *warneri* has pale forehead; *macrorhamphus* is larger, with paler throat and breast. Voice. Song is a gurgling; calls include a contact call "cheur", a rattle heard between mates, a staccato "cree" used during courtship and submissive contexts, an aggressive "zwat", a "zurr" used during fights and as an alarm call, a "krack" used during mobbing of predators, and a "cluck" in territorial contexts.
Habitat. Lowland woodland, savanna, forest clearings, coastal mangroves, farmland, also human habitations, including towns; often near water, such as swamps and rivers. Up to c. 1500 m in Mexico, to c. 2000 m in Ecuador. Forages over open country such as grassland, clearings and water, and around trees.
Food and Feeding. Adult diet in Venezuela c. 50% Hymenoptera (mainly winged ants), 10% each of Odonata, butterflies and moths (Lepidoptera) and termites (Isoptera). Other prey include flies (Diptera), beetles (Coleoptera), other hymenopterans (bees, wasps and parasitic wasps), bugs (both Heteroptera and Homoptera), lacewings (Neuroptera), and grasshoppers and crickets (Orthoptera). Odonata and lepidopterans most important food of nestlings. Feeds alone or in small groups. Flies high up, gliding for much of the time, or alternating gliding with rapid flight. Occasionally feeds on the ground.
Breeding. Mainly Feb-Aug in Mexico; Mar/Apr-Jun/Jul in Central America and N South America, Sept-Dec in S. Solitary or in loose groups; aggressive towards intruders. Male attracts females with "Claiming-Reclaiming display". Nest made of dry grass, twigs, straw or similar fibrous material, even string and cloth, placed in hole in tree, cliff or termite nest, under pier or jetty, in pipe, or frequently in roof or under eaves of building, and birdhouses also used; reported as using mud and straw to reduce size of entrance hole if too large; brings green leaves to nest. Clutch 2-5 eggs; incubation by female, 15-18 days; chicks fed by both sexes, fledging 25-28 days, once only 22 days; young remain near nest for a few days, fed by parents for a week or more.
Movements. Forms large post-breeding flocks and roosts, sometimes thousands of birds, and sometimes with other martins. In N of range may make short post-breeding movements, e.g. away from Atlantic coast; also partially migratory, with non-breeding range extending from Pacific slope of Mexico (S from Nayarit) and Belize S to N Bolivia and C Brazil. Migratory in S of range, where absent mainly Apr-Aug, moving N to as far as S Venezuela, Amazonian Brazil and Surinam. Casual visitor N to S USA (Texas) and Tobago.
Status and Conservation. Not globally threatened. Fairly common to common and widespread in suitable habitat. Often abundant around villages and towns, as readily nests in artificial sites; also roosts in cities, in groups of thousands. Local declines recorded in past, attributed to competition for nest-sites from introduced House Sparrows (*Passer domesticus*).
Bibliography. Anon. (1998a), de Azevedo *et al.* (2000), Belton (1985), Binford (1989), Bitterbaum (1986), Bloch *et al.* (1991), Bond (1971), Canevari *et al.* (1991), Contreras, A.J. 31. Galapagos Martin

Progne modesta

French: Hirondelle sombre **German**: Galapagosschwalbe **Spanish**: Golondrina de Galápagos

Taxonomy. *Progne Modesta* Gould, 1839, San Salvador (James) Island, Galapagos Archipelago.
Forms a superspecies with others of genus apart from *P. tapera*. This species and *P. murphyi* and *P. elegans* often treated as conspecific. Species initially named *Hirundo concolor*, but this name is invalid, as preoccupied. Monotypic.
Distribution. Galapagos Is: present on all islands except Wenman (Wolf), Culpepper (Darwin), Marchena (Bindloe), Pinta (Abingdon), Rábida (Jervis) and Genovesa (Tower).

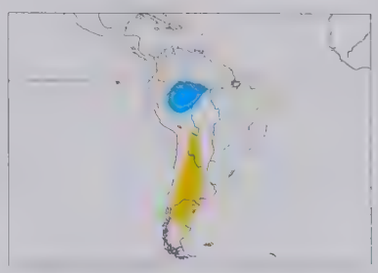
Descriptive notes. 15 cm. Male is dark steel-blue, wings and tail blacker, tail slightly forked. Female has duller upperparts, uniformly dusky brown underparts. Juvenile resembles adult female. Voice. Short, warbling song; twittering flight call "che-cher" or "tchur-tchur", and high-pitched alarm call.
Habitat. Coastal lagoons, forests, and mountains; to 970 m.
Food and Feeding. Diet is known to include butterflies and moths (Lepidoptera). Sometimes feeds low over ground and around houses.
Breeding. Recorded in Mar. Nest made of grass stems and twigs, with a few feathers, in hole in cliff or tree. Clutch 2-3 eggs; no further information available.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common, with small numbers on C & S islands of Galapagos; most common on Isabela (Albemarle).
Bibliography. Beebe (1924a), Best *et al.* (1997), Castro & Phillips (1996), Eisenmann & Haverschmidt (1970), Gifford (1919), Harris (1973, 1982), Heinzel & Hall (2000), Hellmayr (1935), Meyer de Schauensee (1966, 1982), Ridgely & Tudor (1989), Ridgway (1904), Stotz *et al.* (1996), Swarth (1931), Swash & Still (2000).

32. Peruvian Martin

Progne murphyi

French: Hirondelle de Murphy **German**: Peruschwalbe **Spanish**: Golondrina Peruana
Other common names: Chilean Martin

Taxonomy. *Progne murphyi* Chapman, 1925, near Talara, coast of north-west Peru.
Forms a superspecies with others of genus apart from *P. tapera*. Sometimes treated as a race of *P. modesta*. Monotypic.
Distribution. Coastal W Peru and extreme N Chile (Arica).



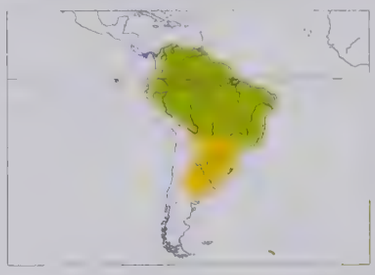
Descriptive notes. 17 cm. Male is dark steel-blue, wings and tail blacker, tail slightly forked; sometimes suggestion of white patch on sides. Distinguished from extremely similar *P. subis* by somewhat longer tail. Female is duller, grey above with steel-blue band across mid-back, dusky centres of crown and hindneck feathers, paler and more uniform underparts, grey-white undertail-coverts. Juvenile resembles adult female. Voice. Not recorded; probably similar to congeners.
Habitat. Open and semi-open areas, including coastal cliffs, grassland, woodland, farmland and human habitations. Mainly along coast but sometimes inland, to 1800 m.
Food and Feeding. Details of diet not documented; probably similar to that of congeners. Frequently glides; flight often slow.
Breeding. Poorly known. Nest in hole in cliff, tree or building. No other information.
Movements. Possibly local post-breeding movements, as numbers in S Peru increase in Jan-Apr.
Status and Conservation. Not globally threatened. Uncommon within small range. Poorly known species; research required in order to determine its ecology and biology.
Bibliography. Clements & Shany (2001), Fjeldså & Krabbe (1990), Hellmayr (1935), Jaramillo (2003), Johnson (1967, 1972), Koepcke (1970), Marín (2004), Meyer de Schauensee (1966, 1982), Mussa & Tala (1996), Ridgely & Tudor (1989), Stotz *et al.* (1996), Zimmer (1955a).

33. Southern Martin

Progne elegans

French: Hirondelle gracieuse **German**: Blauschwalbe **Spanish**: Golondrina Sureña
Other common names: Elegant Martin

Taxonomy. *Progne elegans* S. F. Baird, 1865, Río Bermejo, Argentina.
Forms a superspecies with others of genus apart from *P. tapera*. Sometimes treated as race of *P. modesta*. Hybrids with *P. chalybea* recorded in NW Argentina. Monotypic.
Distribution. Breeds in S Bolivia (S from C Cochabamba and W Santa Cruz) and much of Argentina (generally S to Chubut); migrates N to W Amazonia.
Descriptive notes. 17 cm. Male is dark glossy steel-blue, wings and tail blacker, tail deeply forked. Differs from extremely similar *P. subis* in slightly longer and more deeply forked tail (probably indistinguishable in the field). Female has duller upperparts and dusky brown underparts, feathers extensively pale-margined, appearing scaly, undertail-coverts white with dusky shafts. Juvenile resembles adult female. Voice. Song is a short gurgle; also makes a harsh contact call and an alarm call.



Habitat. Open and semi-open areas, including grassland, woodland, scrub, forest and human habitations; mainly lowlands, but up to 2600 m.
Food and Feeding. Diet known to include Lepidoptera, Odonata and Hymenoptera. Feeds alone or in small groups, both high up and low over ground. Frequently glides; flight often slow.
Breeding. Probably Oct-Feb/Mar. Nest of grass stems and twigs, with a few feathers, placed in hole in cliff, tree or wall or in roof of house; holes made by other species in riverbanks used in Argentina. Clutch 3-5 eggs; no information on incubation and fledging periods.
Movements. Migratory, absent from breeding range mainly Apr-Oct. Forms large post-breeding flocks; appears to spend austral winter mostly in W Amazonia (SE Colombia, NE Peru, W Brazil), but possibly also as far N as E Panama; some may winter in N Argentina, and recorded also in Uruguay. Mixes with *P. chalybea* in winter. Accidental in S USA (S Florida) and Falkland Is.
Status and Conservation. Not globally threatened. Fairly common, especially around towns and cultivated areas.
Bibliography. Anon. (1998a), Babarskas *et al.* (1995), Canaday (2002d), Canevari *et al.* (1991), Chebez *et al.* (1999), Contreras (1995a), Couve & Vidal-Ojeda (2003), Cuello (1985), Eisenmann (1959), Eisenmann & Haverschmidt (1970), Fjeldså & Krabbe (1990), Fraga & Narosky (1985), Guerra (1969), Harris (1998), Hellmayr (1935), Imberti (2003), Johnson (1967), Kaufman (1996), Mazar Barnett & Pearman (2001), Meyer de Schauensee (1966, 1982), Narosky & Di Giacomo (1993), Narosky & Yzurieta (1993), Nellar (1993), Nores *et al.* (1983), de la Peña (1987, 1989), Pereyra (1969), Phillips (1986), Ridgely & Tudor (1989), Sclater & Hudson (1888), Short (1975), Stotz *et al.* (1996), Wetmore (1926), Woods (1988).

34. Brown-chested Martin

Progne tapera

French: Hirondelle tapère **German**: Braunbrustschwalbe **Spanish**: Golondrina Parda

Taxonomy. *Hirundo Tapera* Linnaeus, 1766, America = eastern Brazil (possibly Pernambuco).
Has been placed in a separate genus *Phaeoprogne* because of lack of blue in plumage, similarity of sexes, slender bill, weaker feet, less deeply forked tail and greater feathering on tarsus; DNA-DNA hybridization and cytochrome *b* data, however, indicate close relationship with present genus. Two subspecies recognized.
Subspecies and Distribution.
P. t. tapera (Linnaeus, 1766) - N South America from Caribbean coast and Trinidad S, E of Andes, to Amazonian & NE Brazil, also W of Andes in SW Ecuador (S from Guayas) and NW Peru (Tumbes).
P. t. fusca (Vieillot, 1817) - breeds SE Bolivia and S & E Brazil S to C Argentina (Mendoza, La Pampa, Buenos Aires) and Uruguay; migrates N to N South America and Panama.

Descriptive notes. 16 cm; 30-40 g. Nominate race has crown and upperparts sandy brown, wings and tail darker brown, tail slightly forked; chin, throat and abdomen white, indistinct brown breastband; undertail-coverts long and white. Distinguished from *Riparia riparia* by much larger size. Sexes alike. Juvenile has side of throat more grey-brown, squarer tail. Race *fusca* is larger, darker, has more distinct breastband, dusky marks on lower breast and abdomen. Voice. Song is harsh and guttural with series of gurgling sounds; contact call "chu-chu-chip".
Habitat. Open or semi-open areas with trees, often near water, also human habitations, including towns. Forages over grassland, clearings, rivers and cultivation. Up to c. 1600 m; migrant *fusca* up to 4000 m.
Food and Feeding. Diet includes flies (Diptera), beetles (Coleoptera), bees, wasps and ants (Hymenoptera), termites (Isoptera), bugs (Hemiptera), dragonflies (Odonata), butterflies and moths (Lepidoptera); in Venezuela, nestlings fed mainly with dipterans, hymenopterans and small lepidopterans, with some termites and bugs, but given more large dragonflies as they grew. Feeds alone or in small groups. Flies fast and low over vegetation or water, also slowly around trees or open ground; also high up when feeding on swarming termites and ants.
Breeding. Apr-Jun in Venezuela, Mar-May in Colombia; Nov-Mar in S. Solitary or in small loose groups (of eight bridges along one road, five had only one nest, two had three and one had four); aggressive towards intruders. Nest made from dry grass, lined with feathers, placed in hole in termite nest, earth bank, tree, bridge or building; old nests of Rufous Hornero (*Furnarius rufus*) often used in S (race *fusca*). Clutch 3-5 eggs, usually 4; incubation by female, bouts 2-25 minutes in dry weather, up to 54 minutes in wet, period 14-15 days; nestlings fed by both sexes, fledging c. 28 days; young stay near nest for several days. In one study, 6 of 10 clutches lost to predators or flooding, and 10 of 14 nestlings fledged.
Movements. Nominate race resident. S race (*fusca*) migratory; forms large post-breeding flocks of hundreds or thousands of birds, sometimes with other hirundines. S populations move N to N South America and as far as Panama, where present from Mar to Oct/Nov; also recorded in Costa Rica. Vagrant in USA (Massachusetts, New Jersey, Florida).
Status and Conservation. Not globally threatened. Generally common; uncommon in Ecuador. In S of range, may be limited by availability of hornero nests. Large flocks roosting on buildings are sometimes considered a nuisance by local human inhabitants.

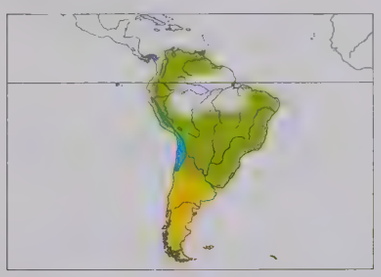
Genus *NOTIOCHELIDON* S. F. Baird, 1865

35. Brown-bellied Swallow

Notiochelidon murina

French: Hirondelle à ventre brun **German**: Mausschwalbe **Spanish**: Golondrina Ventriparda

Taxonomy. *Petrochelidon murina* Cassin, 1853, Ecuador.
Has been placed in genus *Atticora* or in a separate genus *Orochelidon*. Three subspecies recognized.
Subspecies and Distribution.
N. m. meridensis (J. T. Zimmer & Phelps, Sr, 1947) - W Venezuela.
N. m. murina (Cassin, 1853) - Andes in Colombia, Ecuador and Peru.
N. m. cyanodorsalis (Carriker, 1935) - S Peru and C Bolivia.



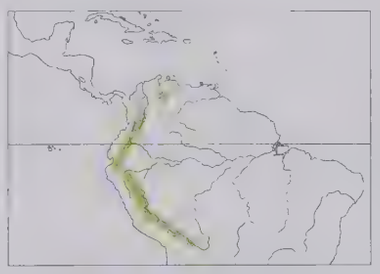
Descriptive notes. 14 cm; 12-5 g. Male nominate race has crown and upperparts blackish with blue-green gloss; wings and tail dark brown, tail moderately forked; underparts sooty grey-brown, black undertail-coverts; underwing-coverts grey-brown. Differs from *N. cyanoleuca* in size and overall dark appearance, from *Haplochelidon andecola* in darker belly and more forked tail. Female is duller. Juvenile is duller than adult, has brown throat, grey-white underparts, shorter tail. Race *meridensis* has bluer upperparts than nominate, with undertail-coverts tipped metallic dark blue in male, brown in female; *cyanodorsalis* has steel-blue gloss on upperparts, undertail-coverts black. Voice. Song is a weak buzzing; also a contact call "tjrip tjirp-tjrip-tjirp", and an alarm call.
Habitat. Open highland country, such as grassland, shrub, elfin forest, *Polylepis* woodland, cultivation, also human habitations; often near water. At 1800-4000 m, mostly above 2500 m.
Food and Feeding. Feeds on aerial insects. Forages alone, in pairs, or in small groups; sometimes with *N. cyanoleuca*, less often with *N. flavipes*. Flight fast and direct, often low over ground, at times high and often in wide circles.
Breeding. Nest-building and/or eggs recorded in Sept-Oct in Colombia and Ecuador; also, individuals in breeding condition in Jan-Aug in WC Andes, and juveniles in Jun-Aug. Solitary or in small loose groups. Nest of dry grass or moss, lined with feathers, placed in hole in cliff, cave or road cutting, in eaves of building, or on beam under bridge. Clutch 2-3 eggs; incubation and fledging periods not documented.
Movements. Probably resident; possibly some local or seasonal movements, e.g. in Venezuela.
Status and Conservation. Not globally threatened. Common or fairly common. Not well known. Present in several protected areas, e.g. Podocarpus National Park (Ecuador).
Bibliography. Best *et al.* (1997), Bloch *et al.* (1991), Chapman (1917a, 1917b, 1917c), Fjeldså & Krabbe (1990), Hellmayr (1935), Hilty (2003), Hilty & Brown (1986), Johnson (1972), Kiff *et al.* (1989), Remsen (1985), Ridgely & Greenfield (2001), Ridgely & Tudor (1989), Ridgely *et al.* (1998), Salaman (1994), Stotz *et al.* (1996), Varty *et al.* (1986), Zimmer (1930, 1955a).

36. Blue-and-white Swallow

Notiochelidon cyanoleuca

French: Hirondelle bleu et blanc **Spanish**: Golondrina Barranquera
German: Schwarzsteißschwalbe
Other common names: Patagonian Swallow (*patagonica*)

Taxonomy. *Hirundo cyanoleuca* Vieillot, 1817, Paraguay.
Sometimes placed in genus *Atticora* or, more usually, in *Pygochelidon*. DNA studies on this species suggest that present genus, although close to former and to *Neochelidon*, is distinct. Three subspecies recognized.
Subspecies and Distribution.
N. c. cyanoleuca (Vieillot, 1817) - E Costa Rica and Panama (highlands), Colombia, Venezuela, Trinidad, the Guianas, and from Ecuador, N & E Peru and C & NE Brazil S to NW Argentina (Tucumán), Paraguay and Uruguay.
N. c. peruviana (Chapman, 1922) - coastal Peru.
N. c. patagonica (d'Orbigny & Lafresnaye, 1837) - breeds from C Chile and C Argentina S to Tierra del Fuego; in non-breeding season N South America (S to N Chile and N Argentina) and S Central America.



Descriptive notes. 12-13 cm; 9-15 g. Has crown and upperparts glossy steel-blue; wings and tail blackish, tail slightly forked; white below, grey wash on sides; undertail-coverts black with blue margins; underwing-coverts sooty-grey. Distinguished from similar *N. flavipes* by white throat and pale sides, larger size. Sexes alike. Juvenile is duller and browner, with pale feather tips on rump, buffy throat, shorter tail. Race *peruviana* is smaller than nominate, with darker sides; *patagonica* is larger than previous, with sides and underwing-coverts paler, and much more white in undertail-coverts. Voice. Song is a series of weak buzzing and squeaking notes; also a contact call "tseet" and an alarm call.
Habitat. Occurs in open and semi-open country, in forest clearings, and around cultivation and human habitations, including large towns. Mostly at middle elevations, to c. 3500 m; in lowlands mainly when not breeding.
Food and Feeding. In Venezuela, adult diet 71% Hymenoptera (mainly flying ants, parasitic wasps), as well as flies (Diptera), beetles (Coleoptera), homopteran bugs and moths (Lepidoptera); nestling diet 27% small dipterans, 22% flying ants, 11% beetles, 15% mayflies (Ephemeroptera), and small numbers of homopterans, moths, parasitic hymenopterans and termites (Isoptera). Diet in Trinidad also includes dipterans, hymenopterans, bugs and beetles. Forages alone or in small, loose groups, mainly at 3-15 m but up to c. 25 m, over open ground and around trees and animals; in poor weather feeds more over water. Sometimes together with *N. murina*, occasionally with *N. flavipes*; also seen to forage with *Haplochelidon andecola*. Flight fast and zigzagging, or more leisurely in circles; about a quarter of flying time spent in gliding.
Breeding. Mostly Jan-Jun/Jul in N, before main rainy season, with peaks in Feb-Apr, Jun-early Aug and Sept-Dec in SE Colombia; mainly Oct-Feb in S of range, but Sept-Dec in Chile and Sept-Mar in Bolivia; one or two broods, usually one at high altitudes. Pair-members may stay together throughout year in N. Solitary or in loose groups; territorial, and aggressive towards intruders. Nest built by both sexes, taking 1 week to 1 month, made of dry grass and feathers, placed in vacant burrow or in hole in tree, bank, ditch, road cutting, rocks, cliff, bridge, building, well or lamppost; holes made by Common Miner (*Geositta cunicularia*) in viscacha (*Lagostomus*) burrows often used in S of range. Clutch 2-4 eggs in N, 3-6 in S; incubation by both sexes, period c. 15 days; both also feed nestlings, average of 3 visits per hour per nestling, fledging period 26-27 days; fledglings fed by parents near nest for several days.
Movements. Resident in N, migratory in S. Forms large post-breeding flocks of tens or hundreds. Race *patagonica* migrates N, departure from breeding grounds Jan-Mar; in non-breeding season present from Panama, and casually from farther N (to Chiapas, in S Mexico), S to N Chile and N Argentina; main return to breeding grounds in Aug-Sept. Elevational shifts in N, e.g. in Venezuela.
Status and Conservation. Not globally threatened. Widespread and common; sometimes very abundant, especially in highlands and in S of range. A common hirundine in towns and cultivated areas. Readily takes advantage of artificial nest-sites; has probably benefited from urban expansion.
Bibliography. Anon. (1998a), Arnold *et al.* (1983), Bloch *et al.* (1991), Canevari *et al.* (1991), Chebez & Bertonatti (1994), Chebez *et al.* (1999), Contreras (1995a), Couve & Vidal-Ojeda (2003), Davies *et al.* (1994), ffrench (1991), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Flores & Capriles (1998), Fraga & Narosky (1985), Freeman (1922), Harris (1998), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Hellmayr (1935), Hilty (1997, 2003), Hilty & Brown (1986), Howell & Webb (1995a), Humphrey *et al.* (1970), Jaramillo (2003), Johnson (1967, 1972), Klimaitis & Moschione (1987), Koepcke (1963, 1970), von Lehmann (1960), Miller (1963), Olrog (1958), Parker & Goerck (1997), Paynter & Álvarez del Toro (1957), de la Peña (1987, 1989), Perry *et al.* (1997), Remsen (1985), Ridgely & Greenfield (2001), Ridgely & Tudor (1989), Riveros (1989), Rocha & Quiroga (1998), do Rosário (1996), Salaman (1994), Sheldon & Winkler (1993), Sick (1993), Skutch (1952, 1960, 1985), Slud (1964), Souza *et al.* (1998), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tostain *et al.* (1992), Turner (1983b), Vuilleumier (1985), Willis & Eisenmann (1979), Wilson (1926), Wolf (1976), Zimmer (1930, 1955a).

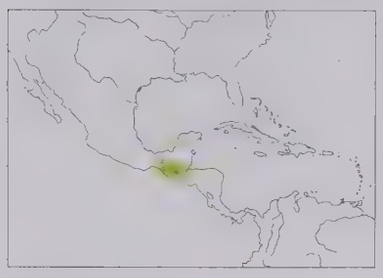
37. Pale-footed Swallow

Notiochelidon flavipes

French: Hirondelle de Chapman **German**: Blassfußschwalbe **Spanish**: Golondrina Paticlara
Other common names: Cloudforest Swallow

Taxonomy. *Pygochelidon flavipes* Chapman, 1922, Maraynioc, 10,850 feet [c. 3300 m], Junín, Peru.
Sometimes placed in genus *Pygochelidon*. Monotypic.
Distribution. Andes in W Venezuela (Trujillo S to S Táchira), W Colombia, and on E slope from Ecuador S to C Bolivia.

Descriptive notes. 12 cm; 8-8-12 g. Has crown and upperparts blackish with blue gloss; wings and tail blackish-brown, tail slightly forked; throat pale rufous, breast and abdomen white, side of body brown, undertail-coverts dark steel-blue; underwing-coverts blackish-brown. Distinguished from *N. cyanoleuca* by rufous throat, darker sides, smaller size. Sexes similar, female possibly slightly paler. Juvenile undescribed; one immature had pale edges of undertail-coverts. Voice. Calls include a sharp "tszeet" and a trilled "tr-e-e-e-e-d", unlike buzzy notes of *N. cyanoleuca*.
Habitat. Upper cloudforest and elfin forest, and forest edge. Mostly at 2400-3000 m, rarely down to 2000 and up to 3600 m; in Venezuela 2200-2400 m, once as low as 1550 m.
Food and Feeding. Diet unknown. Feeds in small groups, typically of 2-15 individuals, occasionally up to 50; hunts over forest, in clearings and along forest edge. Sometimes seen with *N. murina* or *N. cyanoleuca*, but associated more with forest habitat than are those. Flight fast, faster than that of *N. cyanoleuca*, and direct or erratic, often repeatedly backtracking.
Breeding. Unknown. Males in breeding condition in Jul-Sept. May nest in hole in moss clump on tree or in road cutting. Male with brood patch suggests that both sexes incubate.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon. Was thought to be rare, but recent records suggest that it may be widespread in Andes S to W Santa Cruz, in Bolivia, and possibly fairly common locally. First recorded in Venezuela (Mérida) in 1985, since when many records and sight reports from Trujillo S to Táchira; numerous recent records from Guaramacal National Park (Trujillo). Occurs at Cock-of-the-Rock Lodge, in Peru. Has possibly been often overlooked in the past because of its similarity to *N. cyanoleuca*.
Bibliography. Best *et al.* (1997), Bloch *et al.* (1991), Carrión & Sibley (1992), Fjeldså & Krabbe (1990), Hilty (1999, 2003), Hilty & Brown (1986), Krabbe *et al.* (1997), Lentino (1988), López (1999a), Parker & O'Neill (1980), Parker & Rowlett (1984), Remsen (1985), Ridgely & Greenfield (2001), Ridgely & Tudor (1989), Ridgely *et al.* (1998), Ryan & Lentino (1995), Stotz *et al.* (1996), Zimmer (1955a).



On following pages: 38. Black-capped Swallow (*Notiochelidon pileata*); 39. Andean Swallow (*Haplochelidon andecola*); 40. White-banded Swallow (*Atticora fasciata*); 41. Black-collared Swallow (*Atticora melanoleuca*); 42. White-thighed Swallow (*Neochelidon tibialis*); 43. Northern Rough-winged Swallow (*Stelgidopteryx serripennis*); 44. Southern Rough-winged Swallow (*Stelgidopteryx ruficollis*); 45. Tawny-headed Swallow (*Alopochelidon fucata*).

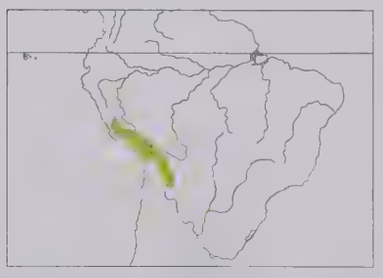
38. **Black-capped Swallow**

Notiochelidon pileata

French: Hirondelle à tête noire **German**: Kappenschwalbe **Spanish**: Golondrina Cabecinegra
Other common names: Coban Swallow

Taxonomy. *Atticora pileata* Gould, 1858, Guatemala.
Sometimes placed in genus *Atticora*. Monotypic.
Distribution. Highlands of S Mexico (Chiapas), S Guatemala and adjacent W Honduras and W El Salvador.

Descriptive notes. 12-13 cm. Has forehead to hindneck black with blue gloss; upperparts grey-brown, darker on rump and uppertail-coverts; wings and tail brownish-black, tail moderately forked; chin and throat white with brown flecks, breast and abdomen white, sides grey-brown, undertail-coverts blackish; underwing-coverts grey-brown. Distinguished from other hirundines by combination of brown upperparts and black head and undertail-coverts. Sexes alike. Juvenile is duller and browner, throat buffy, pale feather edges on rump and secondaries. Voice. Song is a buzzing "bzeet"; also a nasal "sreet", a buzzy "zrrieh" and a "tri-i-it".
Habitat. Open woodland, woodland edge, clearings, cultivation, and human habitations, including towns. At 1600-3100 m, at times down to 1000 m.
Food and Feeding. Diet unknown. Feeds alone or in small groups, often low over ground. Flight rapid, but with frequent periods of gliding. At one site, hunted within a few hundred metres of nests.
Breeding. Feb-Apr in Mexico, Apr-Jul in Guatemala. Solitary or in small, loose groups. Nest built by both sexes, in one case taking 5 days, of dry leaves, pine (*Pinus*) needles, fine twigs and feathers, sometimes also green leaves, and mud also recorded, placed in hole in riverbank, cliff, cave, rocks, road cutting or building; old burrows of other species, such as motmots (Momotidae), used. Clutch of 4 eggs recorded; incubation and fledging periods not documented; both sexes feed nestlings, one pair made 36 trips in course of an hour.
Movements. Some post-breeding movements. Recorded in mountains of Honduras as non-breeding visitor, and in El Salvador as a summer visitor.
Status and Conservation. Not globally threatened. Restricted-range species: present in North Central American Highlands EBA. Locally common to fairly common.
Bibliography. Amadon & Eckelberry (1955), Baepler (1962), Blake, E.R. (1953), Dearborn (1907), Friedmann *et al.* (1950), Hellmayr (1935), Howell & Webb (1995a), Komar & Domínguez (2001), Land (1970), Marshall (1943), Monroe (1968), Ridgway (1904), Skutch (1960), Stotz *et al.* (1996), Thurber *et al.* (1987), Wagner (1951), Wetmore (1941).



Genus *HAPLOCHELIDON* Todd, 1929

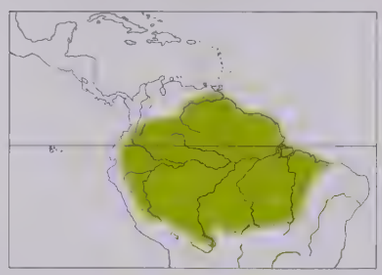
39. **Andean Swallow**

Haplochelidon andecola

French: Hirondelle des Andes **German**: Andenschwalbe **Spanish**: Golondrina Andina
Other common names: Andean Cliff Swallow (when placed in *Petrochelidon*)

Taxonomy. *Hirundo andecola* d'Orbigny and Lafresnaye, 1837, La Paz, Bolivia.
Until recently was placed in *Petrochelidon* or *Hirundo*, but now considered not related to either of those groups. DNA-DNA hybridization data strongly indicate that it belongs with the "core martin group" and is close to *Notiochelidon*, *Atticora* and *Neochelidon*. Has sometimes been included in *Stelgidopteryx*, and vocalizations similar, but lacks "serrated" edge of outer primary of that genus. Two subspecies recognized.
Subspecies and Distribution.
H. a. oroyae (Chapman, 1924) - C Peru.
H. a. andecola (d'Orbigny & Lafresnaye, 1837) - Andes in S Peru, extreme N Chile (Arica, Tarapacá), C & S Bolivia and NW Argentina (Salta, Jujuy).

Descriptive notes. 14 cm; 14-19 g. Has crown and upperparts glossy blue-black, rump light brown; wings and tail brownish-black, tail almost square; underparts grey-brown, whiter on abdomen and undertail-coverts; underwing-coverts grey-brown. Differs from *Notiochelidon murina* in pale rump and paler underparts, from *N. cyanoleuca* in less blue upperparts and darker underparts. Sexes alike. Juvenile is duller and browner than adult, rump more rufous, pale tips of wing-coverts and tertials. Race *oroyae* is larger and bluer than nominate. Voice. Song is a brief, harsh "trrrt"; also a contact call "trui".
Habitat. Open mountainous country, breeding near ravines, cliffs or human habitations; forages over open areas, such as rivers, pastures, roads and hillsides. Mostly at 2500-4400 m; observed down to 1450 m and up to 4600 m.
Food and Feeding. Dietary details not known; aerial insects. Feeds alone or, more usually, in small groups of up to c. 20 individuals; flock of c. 100 feeding over a river in Aug (presumably outside breeding season). Recorded both low above ground, at c. 1-5 m, occasionally coming down to ground, and high up, at 30-200 m; flight slow, with periods of gliding. Also feeds around grazing animals, and has been observed with *N. cyanoleuca*.
Breeding. Possibly Sept-Oct in Peru and Sept-Dec in Argentina; Dec-Mar in Bolivia. In loose groups; one was of 3-4 nests in a roof, another of three pairs apparently nesting, and a third of five birds at a single hole. Nest in hole in escarpment wall, cliff or road cutting, or in eaves or roof of building, one hole in cliff was c. 2 m above ground; reported to enlarge or dig a hole itself. Clutch size and incubation and fledging periods not documented.
Movements. May make some post-breeding movements. At one site in Peru, was present in Sept-Oct but absent in Dec.
Status and Conservation. Not globally threatened. Locally common within relatively limited range. Several thousand recorded at Laguna Tacahua, in Peru. Rather poorly known species.
Bibliography. Chebez *et al.* (1999), Fjeldså (1987), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Flores & Capriles (1998), Hellmayr (1935), Hennessey, Herzog & Sagot (2003), Jaramillo (2003), Johnson (1967, 1972), Marín (2004), Mazar Barnett & Pearman (2001), Meyer de Schauensee (1966, 1982), Morrison (1939), Niethammer (1956), Parkes (1993a), Ridgely & Tudor (1989), Sheldon & Winkler (1993), Stotz *et al.* (1996), Zimmer (1955a).



Genus *ATTICORA* Boie, 1844

40. **White-banded Swallow**

Atticora fasciata

French: Hirondelle à ceinture blanche **Spanish**: Golondrina Fajiblanca
German: Weißbandschwalbe

Taxonomy. *Hirundo fasciata* J. F. Gmelin, 1789, Cayenne.
DNA data suggest that this genus and *Neochelidon* are sister-taxa. Size decreases clinally from N to S. Monotypic.
Distribution. E Colombia, S & E Venezuela and the Guianas S to E Ecuador, E Peru, Amazonian Brazil (E to E Pará, S to Rondônia and N Mato Grosso) and N Bolivia.

Descriptive notes. 15 cm; 12-16 g. Plumage pattern and deeply forked tail distinctive. Is mostly glossy blue-black, except for broad white breastband, black wings and tail; white feathers on thighs; underwing-coverts blackish-brown. Sexes alike. Juvenile is duller, with dusky underparts, pale feather edges on wings and underparts, shorter tail. Voice. A buzzy "bzrrrt" often uttered in flight.
Habitat. Upper reaches of forested clear or black-water rivers; forages over water, in clearings, forest edge, and grassy areas with bushes. Mostly to c. 1000 m; to 700 m in Venezuela.
Food and Feeding. Diet includes flies (Diptera), hymenopterans including parasitic wasps, sawflies (Symphyta), ants and bees, also beetles (Coleoptera) and homopteran bugs. Forages alone or in small groups. Flies fast and low over water, sometimes over forest canopy. Sometimes with *A. melanoleuca* or *Tachycineta albiventer*, but stays closer to vegetation and rocks than do those.
Breeding. Poorly known. Evidence of breeding in Feb-Mar in Colombia, Dec in Surinam and Sept in Bolivia. Solitary or in loose groups. Nest of dry grass, placed in hole or burrow in riverbank; not known whether it digs own holes or uses those of other species. Clutch 4-5 eggs; no information on incubation and fledging periods.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Generally uncommon or locally common; common in Peru. Present in several protected areas, e.g. Podocarpus National Park (Ecuador), and Rio Cristalino Forest Reserve (Brazil).
Bibliography. Bloch *et al.* (1991), Haverschmidt (1968), Haverschmidt & Mees (1994), Hellmayr (1935), Hilty (2003), Hilty & Brown (1986), Naumberg (1930), Niethammer (1956), Perry *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1989), Robinson (1997), Sheldon & Winkler (1993), Sick (1993), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tostain *et al.* (1992), Zimmer, J.T. (1955a), Zimmer, K.J. & Hilty (1997), Zimmer, K.J. *et al.* (1997).

41. **Black-collared Swallow**

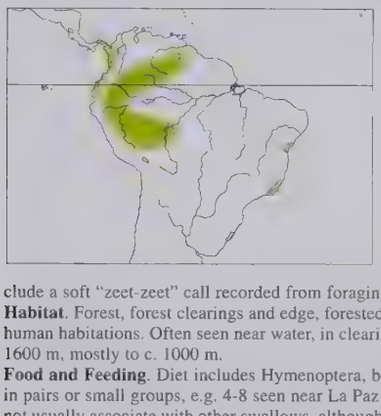
Atticora melanoleuca

French: Hirondelle des torrents **Spanish**: Golondrina Acollarada
German: Halsbandschwalbe

Taxonomy. *Hirundo melanoleuca* Wied, 1820, Rio Grande do Belmonte, Bahia, Brazil.
DNA data suggest that this genus and *Neochelidon* are sister-taxa. Monotypic.
Distribution. Extreme E Colombia (E Vichada, E Guainía, E Vaupés), S & E Venezuela (Amazonas, Bolívar, Delta Amacuro), the Guianas, and locally in Amazonian & S Brazil (mainly upper R Negro area, also Amapá and, S of Amazon, along drainages of rivers Madeira, Tapajós, Xingú and Tocantins, also isolated records from SE Bahia, and from upper R Paraná in S Goiás); also on Brazil-Argentina border (Iguaçu Falls).

Descriptive notes. 14 cm; 10-12 g. Combination of plumage pattern and deeply forked tail distinctive. Has glossy blue-black crown and upperparts, blackish wings and tail; white below, blue-black breastband, blue-black undertail-coverts; underwing-coverts blackish-brown. Sexes alike. Juvenile is duller and browner than adult, with dirty white underparts, shorter tail. Voice. A buzzy "jit" has been recorded.
Habitat. Rivers, especially near waterfalls and rapids; to c. 300 m.
Food and Feeding. Diet includes flies (Diptera), beetles (Coleoptera), ants and parasitic wasps (Hymenoptera), and homopteran bugs. Forages alone or in small groups, sometimes with other swallows, e.g. *A. fasciata*. Flies fast, low over water, or circles more slowly above surface; also glides high over river or forest.

Breeding. Poorly known. Recorded Feb-Mar in Venezuela (Orinoco region) and Feb in Surinam. Solitary or in loose groups. Nest of dry grass, lined with feathers, placed in hole c. 2 m up in rock or riverbank. Clutch 3 eggs recorded; no information on incubation and fledging periods.
Movements. Probably mainly resident. Some irregular movement; at site in NW Amazonas (Venezuela), common in Dec-Mar, when water levels low, but scarce or absent in Jun, when levels high.
Status and Conservation. Not globally threatened. Locally uncommon or fairly common. Most common along black-water rivers of Venezuela, the Guianas and N Brazil (upper R Negro); very local and less common away from such rivers, e.g. only small numbers at Iguaçu Falls (S Brazil-NE Argentina). Distribution poorly known; range highly fragmented.
Bibliography. Canevari *et al.* (1991), Chebez *et al.* (1999), Cherrie (1916), Contreras (1995a), Fraga & Narosky (1985), Friedmann (1948), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Hellmayr (1935), Hilty (2003), Hilty & Brown (1986), Naumberg (1930), Parker & Goerck (1997), de la Peña (1989), Ridgely & Tudor (1989), Sick (1993), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tostain *et al.* (1992), Zimmer & Hilty (1997).



Genus *NEOCHELIDON* P. L. Sclater, 1862

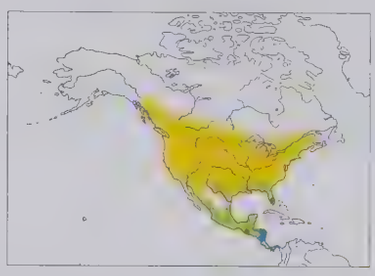
42. **White-thighed Swallow**

Neochelidon tibialis

French: Hirondelle à cuisses blanches **Spanish**: Golondrina Patiblanca
German: Zwergschwalbe

Taxonomy. *Petrochelidon(?) tibialis* Cassin, 1853, type locality unknown, probably vicinity of Rio de Janeiro, Brazil.
DNA data suggest that this genus and *Atticora* are sister-taxa. Three subspecies recognized.
Subspecies and Distribution.
N. t. minima Chapman, 1924 - E Panama, W Colombia and W Ecuador (S to E Guayas).
N. t. griseiventris Chapman, 1924 - S & SE Venezuela (Amazonas, SE Bolívar), E & S Colombia, E Ecuador, E Peru, W Brazil and N Bolivia.
N. t. tibialis (Cassin, 1853) - E Brazil (E Bahia, Espírito Santo, Rio de Janeiro, E São Paulo).

Descriptive notes. 12 cm; c. 10 g. Nominate race is brownish-black with slight green sheen above, rump grey-brown; wings and tail brownish-black, tail slightly forked; underparts, including underwing-coverts, grey-brown, undertail-coverts blackish-brown; diagnostic tuft of white feathers on lower leg (but difficult to see in field). Distinguished from *Stelgidopteryx ruficollis* by small size and all-dark appearance. Sexes alike. Juvenile resembles adult, but with pale feather edges. Race *minima* is smaller, and darker brown; *griseiventris* is larger, with glossier upperparts, greyer rump and underparts. Voice. Calls include a soft "zeet-zeet" call recorded from foraging birds and "chit-it chee-dee-dit".
Habitat. Forest, forest clearings and edge, forested rivers, semi-open country with scattered trees, human habitations. Often seen near water, in clearings around farms and along roads. Lowlands to 1600 m, mostly to c. 1000 m.
Food and Feeding. Diet includes Hymenoptera, beetles (Coleoptera), bugs (Hemiptera). Forages in pairs or small groups, e.g. 4-8 seen near La Paz (Bolivia), up to 12 in Amazonas (Brazil); does not usually associate with other swallows, although sometimes with *Stelgidopteryx*. Flies in circles only c. 1 m above ground; flight erratic and bat-like. In wet weather, gleans insects from underside of leaves.
Breeding. Poorly known. Evidence of breeding in Jan and Mar-May in Colombia, and Feb, Apr-Jun and Sept in Panama. Nest of dry grass, placed in natural hole or one made by other species in tree or bank. No other information.
Movements. Poorly known. Apparently resident in Panama and in Amazonia. May make some local movements; present in upper Anchicayá Valley, in Colombia, only in Apr and Jul-Nov.
Status and Conservation. Not globally threatened. Uncommon or locally fairly common; more common W of Andes; uncommon to rare, and local, in Venezuela. Limits of distribution not well known; perhaps more widespread, both N & S of Amazon, than currently thought.
Bibliography. Bloch *et al.* (1991), Haverschmidt & Mees (1994), Hellmayr (1935), Hilty (1997, 2003), Hilty & Brown (1986), Parker & Goerck (1997), Parker & Remsen (1987), Parker *et al.* (1991), Peres & Whittaker (1991), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1989), Robinson (1997), Salaman (1994), Sclater & Salvin (1879), Scott & Brooke (1985), Sheldon & Winkler (1993), Sick (1993), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tostain *et al.* (1992), Wetmore *et al.* (1984), Willis & Oniki (1985), Zimmer, J.T. (1955a), Zimmer, K.J. *et al.* (1997).



Genus *STELGIDOPTERYX* S. F. Baird, 1858

43. **Northern Rough-winged Swallow**

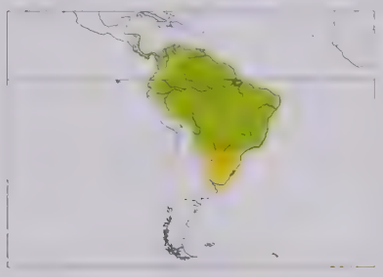
Stelgidopteryx serripennis

French: Hirondelle à ailes hérissées **Spanish**: Golondrina Aserrada
German: Graukehlschwalbe
Other common names: Rough-winged Swallow (when treated as conspecific with *S. ruficollis*); Ridgway's/Yucatan Rough-winged Swallow (*ridgwayi*, *stuarti*)

Taxonomy. *Hirundo serripennis* Audubon, 1838, Charleston, South Carolina, USA.
Formerly considered conspecific with *S. ruficollis*, and race *decolor* of latter has been regarded as intermediate between the two species, but they are separated altitudinally where ranges overlap in Costa Rica. Present species sometimes treated as monotypic; races intergrade and borders between them (and degree of overlap) uncertain, also N-S cline in coloration, and tendency for paler forms in SW USA and NW Mexico, also size increases N to S and wing longer towards NW; *fulvipennis* possibly not separable. Conversely, *ridgwayi* and *stuarti* sometimes regarded as constituting a separate species. Proposed race *aphracta* (W Great Basin region of USA), supposedly dark above and with greyer throat, considered undiagnosable. Six subspecies tentatively recognized.
Subspecies and Distribution.
S. s. serripennis (Audubon, 1838) - SE Alaska, and from S Canada (C British Columbia, C Alberta, C Saskatchewan, S Manitoba, W & S Ontario E to SW New Brunswick and SW Nova Scotia) S in USA to C California, N Nevada, New Mexico, C Texas and SW Florida; winters mostly SW Mexico and Florida S to C Panama.
S. s. psammochroa Griscom, 1929 - S California, S Nevada, SW Utah, SW Arizona, S New Mexico and S Texas S to S & NE Mexico (S through N coastal plains and possibly interior highlands to SW Oaxaca and Tamaulipas), possibly also S along coast to El Salvador; winters C Mexico S to Panama.
S. s. fulvipennis (P. L. Sclater, 1860) - C & S Mexico (lowlands and middle elevations from C Veracruz, E Oaxaca and E Chiapas) S to Costa Rica.
S. s. stuarti Brodkorb, 1942 - S Mexican lowlands (S from S Veracruz, Oaxaca and Chiapas) S to E Guatemala.
S. s. ridgwayi Nelson, 1901 - N Yucatán Peninsula (S to N Campeche and C Quintana Roo).
S. s. burleighi A. R. Phillips, 1986 - Belize and Guatemala (S Yucatán Peninsula).

Descriptive notes. 12·5-14·5 cm; 10·3-18·3 g. Male nominate race is grey-brown above, rump with paler feather edges; wings and tail dark grey-brown, stiff recurved barbs on outer web of outer primary, tail square-ended; pale grey-brown chin to breast, sides and flanks, throat buffy in fresh plumage, rest of underparts, including undertail-coverts, dull white; underwing-coverts light grey-brown. Differs from very similar *S. ruficollis* in having duller throat. Sexes similar, but female lacks recurved barbs on outer primary. Juvenile has cinnamon edges on upperpart feathers. Race *psammochroa* is paler than nominate; *fulvipennis* is darker above, especially on crown; *ridgwayi* has whitish spot above lores, is darker above, and longest undertail-coverts dark; *stuarti* is very like last, but generally even darker above with rufescent wash on breast and flanks; *burleighi* is darkest and brownest race. Voice. Territorial call is a series of fast "brrrt" notes; other calls include an alarm call, high notes uttered during aggression; a soft note uttered by female near nest; in Costa Rica also a trill and a gurgling "zhrit" recorded.
Habitat. Rocky gorges or open areas with exposed banks of gravel, clay or sand, such as road cuttings, streams, gravel pits; also coastal. Often near water. To c. 2500 m; in Costa Rica, generally at higher elevations than *S. ruficollis*. Feeds over open country and wetlands when not breeding. Roosts in marshes, mangroves, sugar-cane fields.
Food and Feeding. In samples taken throughout North America, diet 33% flies (Diptera), 31% Hymenoptera (mainly ants), 15% bugs (Hemiptera), 15% beetles (Coleoptera); other prey includes Orthoptera, Odonata, moths and caterpillars (Lepidoptera), mayflies (Ephemeroptera), spiders (Araneae). One report of several individuals eating cracked corn. Nestling diet mainly dipterans and hymenopterans. Flight direct, with slow deliberate wingbeats, often low over water or ground. Occasionally lands to feed on abundant source of food on ground, e.g. midges at lake edge, larvae in dead fish, or flies on waterfowl droppings.
Breeding. Egg-laying mid-May to mid-Jun in NE, early Jun to early Jul in NW; from Mar/Apr in Middle America; fledging Jul-Aug in N; single-brooded. Singly or in groups of 2-25 pairs, burrows often a few metres apart, often at edge of *Riparia riparia* colony; aggressively defends burrow and its immediate vicinity. Male follows female closely during nest-building and egg-laying. Burrow 0·2-30 m above ground (mostly 0·9-4·5 m), 20-200 cm long (mostly 30-100 cm), in clay, sand or gravel bank, occasionally excavated by bird itself, but mostly vacant burrow of other species, such as *R. riparia*, kingfisher (Alcedinidae), motmot (Momotidae), ovenbird (Furnariidae) or small mammal, used, sometimes modified by further digging; burrow sometimes reused in successive years; also uses hole in other vertical surface, including artificial ones (e.g. pipe, gutter, wall, culvert, bridge, wharf, boat and semi-trailer), rarely in tree or cave, and occasionally a ledge protected by overhang used; nest cup made from variety of vegetable fibres, such as grass, straw, rootlets, twigs, leaves, bark, pine (*Pinus*) needles, moss and dung, lined with grass, some green material included, especially in lining, all or nearly all of material collected by female, building takes 3-20 days, usually up to 7 days. Clutch 4-8 eggs, mostly 5-7, clutch size decreases with decreasing latitude, average 6·25 eggs in N USA (Michigan), 4·7 in Costa Rica; incubation by female, attentive periods 0·5-22·5 minutes, duration 16 days, in Central America possibly up to 18 days; hatching over 0·5-3·5 days, chicks brooded at high level for first few days, fed 10-20 times per hour per parent, sexes bring food about equally but female's contribution drops in last third of nestling period; fledging 17-21·5 days, average 19 days; length of dependency of fledglings unclear, estimates range from few days to several weeks, young do not usually return to burrow. Fledging success 61%; causes of losses include flooding during high spring water, erosion of nest-site, hypothermia and starvation in bad weather, and predation. Oldest recorded bird at least 5 years.
Movements. N populations are medium-distance migrants; resident in S. Forms flocks after breeding, often of hundreds of individuals, and often with other species (especially *R. riparia*). N populations winter from S USA (from S California, lower Colorado Valley and C Arizona, increasingly so since 1950s) S to Panama, but extent of wintering in USA unclear because of presence of late/early migrants (nominate race may return to California in Nov-Dec); population in W of range migrates S in Aug-Nov; that in E in Jul-Oct, but migration across Gulf of Mexico delayed until moult of flight-feathers complete, and some (possibly juveniles, which moult later than adults) winter in SE USA. Regularly recorded in Caribbean in winter. Arrival back on breeding grounds mid-Feb (S California) to late Apr (Ontario); may return to same breeding area in successive years. Populations in Mexico and farther S resident, with some local post-breeding movements; e.g. *fulvipennis* in El Salvador and Costa Rica moves to lowland areas after breeding. Vagrants recorded N to Alaska, Yukon and Newfoundland.
Status and Conservation. Not globally threatened. Population size estimated at 15,000,000 birds; more abundant in W than in E. Since 19th century breeding range has expanded N in Midwest and New England, continuing into Maine, New Brunswick and Nova Scotia; also S in Florida since 1930, and along coast of North Carolina since early 1980s. Common to fairly common but local breeder in Mexico and N Central America; less common on Mexican Plateau. Distribution patchy; breeding numbers may be limited by availability of nest-sites. Population trends in North America

variable: no significant change in 1966-1989, but significant decline of 19·6% in 1988-1989, and significant increases in E & C North America in 1965-1979. Has probably benefited from new nest-sites created by human activity, such as canal banks, quarries and road cuttings; 30-60% of nests in Canada in human-created sites; can be attracted to breed by provision of artificial nesting tubes set into vertical bank. Habitat destruction can affect populations locally.



Bibliography. Amos (1991), Arendt (1992), Armstrong (1983), Baicich & Harrison (1997), Beecher *et al.* (1986), Behle (1985), Bent (1942), Best (1977), Binford (1989), Blake, C.H. (1953), Blake, F.G. 44. **Southern Rough-winged Swallow**

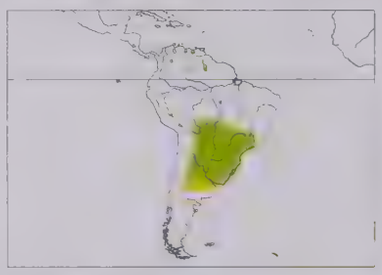
Stelgidopteryx ruficollis

French: Hirondelle à gorge rousse **German**: Zimtkehlschwalbe **Spanish**: Golondrina Gorgirrufa
Other common names: Rough-winged Swallow (when treated as conspecific with *S. serripennis*)

Taxonomy. *Hirundo ruficollis* Vieillot, 1817, Brazil.
Formerly considered conspecific with *S. serripennis*, and race *decolor* has been regarded as intermediate between the two species, but they are separated altitudinally where ranges overlap in Costa Rica. Present species sometimes treated as monotypic, as races intergrade, also depth of plumage colour varies clinally, becoming generally darker from N to S & E. Birds from Surinam named as race *cacabata*, but description believed to have been based on migrants of nominate race. Four subspecies usually recognized.
Subspecies and Distribution.
S. r. decolor Griscom, 1929 - W Costa Rica and W Panama.
S. r. uropygialis (Lawrence, 1863) - Caribbean lowlands S from E Honduras, Pacific lowlands of E Panama, W Colombia, Ecuador and NW Peru.
S. r. aequalis Bangs, 1901 - N Colombia, W Venezuela and Trinidad.
S. r. ruficollis (Vieillot, 1817) - SE Colombia, E Venezuela, the Guianas and Brazil S to E Peru, Bolivia, N & NE Argentina (S to Salta, Formosa, Entre Ríos and N Buenos Aires) and Uruguay.

Descriptive notes. 13 cm; 14-18 g. Male nominate race is mainly dark grey-brown, slightly darker on crown than on back, slightly paler rump; wings and tail blackish-brown, stiff recurved barbs on outer web of outer primary, tail square-ended; throat cinnamon, rest of underparts dark grey-brown, becoming yellowish on abdomen, with undertail-coverts white; underwing-coverts dark grey-brown. Distinguished from *S. serripennis* by brighter throat, from *Alopochelidon fucata* by grey-brown head and paler rump. Sexes similar, but female lacks recurved barbs on outer primary. Juvenile has duller throat, pale edges of feathers on back. Race *decolor* is palest, with dark shaft streaks below; *uropygialis* is darker than previous, rump conspicuously whitish; *aequalis* is light brown above, rump pale, throat tawny-buff. Voice. Similar to *S. ruficollis* but lower-pitched and less harsh (*uropygialis*); calls include twitters or buzzy notes at nest-site, most commonly an upslurred "suree".
Habitat. Open country, particularly near water, also forest clearings, and along rivers. Usually below 1000 m, locally to 2000 m, and recorded to 3600 m; in Costa Rica, generally at lower elevations than *S. serripennis*.
Food and Feeding. Diet includes flies (Diptera), beetles (Coleoptera), heteropteran bugs, and flying ants and other Hymenoptera. Feeds alone or in small groups, generally low or at medium height over ground or water. Flight usually direct, with slow, deliberate wingbeats.
Breeding. Mar/Apr-Jun in Central America and Trinidad, Feb-Jul in Colombia; single-brooded. Solitary or in small loose groups; aggressive towards intruders. Nest of dry grass, leaves and feathers, in hole or old burrow in riverbank, quarry or road cutting; burrow usually made by other species, e.g. motmot (Momotidae), but has been recorded as digging. Clutch 4-6 eggs in Central America, 3-6 in Trinidad, 3-5 in S of range; incubation by female, 15-18 days; chicks fed by both sexes, fledging 18-21 days; young stay near nest-site and are fed for several days, once for at least 25 days.
Movements. Apparently resident in N, pairs staying near nest-site; migratory in S. Forms large flocks after breeding. Nominate race has been recorded in N of breeding range (e.g. Colombia, Surinam) in non-breeding season, and likely to occur in neighbouring countries, but extent of non-breeding distribution not known. Vagrant in Falkland Is.
Status and Conservation. Not globally threatened. Generally common and widespread; sometimes sparse and local. Restricted to areas with natural nest-sites, as it does not often use artificial ones.

Bibliography. Belton (1985), Bloch *et al.* (1991), Canevari *et al.* (1991), Capper *et al.* (2000), Chebez *et al.* (1999), Davies *et al.* (1994), Faaborg & Terborgh (1980), ffrench (1991), Fjeldså & Krabbe (1990), Fraga & Narosky (1985), Freeman (1922), Griscom (1929), Haverschmidt (1968, 1982), Haverschmidt & Mees (1994), Hayes (1995), Hellmayr (1935), Hespenheide (1975, 1980), Hilty (1997, 2003), Hilty & Brown (1986), Miller (1963), Monroe (1968), Moojen *et al.* (1941), Parker & Goerck (1997), de la Peña (1989), Pereyra (1969), Perry *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1989), Robinson (1997), do Rosário (1996), Salaman (1994), Short (1975), Skutch (1981, 1985), Slud (1964), Souza *et al.* (1998), Stiles (1980, 1981), Stiles & Skutch (1989), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tostain *et al.* (1992), Tramer (1980), Wagner (1951), Wetmore *et al.* (1984), Willis (1980), Zimmer, J.T. (1930, 1955a), Zimmer, K.J. & Hilty (1997), Zimmer, K.J. *et al.* (1997).



Genus *ALOPOCHELIDON* Ridgway, 1903

45. **Tawny-headed Swallow**

Alopochelidon fucata

French: Hirondelle fardée **German**: Fuchsschwalbe **Spanish**: Golondrina Cabecicastaña

Taxonomy. *Hirundo fucata* Temminck, 1822, Brazil.
Genus sometimes merged with *Stelgidopteryx*, but lacks serrated wing edge of latter. Monotypic.
Distribution. SE Peru (Cuzco), and from E Bolivia (S from NE Cochabamba and Santa Cruz) and S Brazil (S from Mato Grosso, S Goiás and Minas Gerais) S to N Argentina (S to Mendoza and Buenos Aires) and Uruguay; also N South America in non-breeding season.

Descriptive notes. 12 cm; 13-15 g. Has tawny-rufous top of head, darker on central crown, tawny-buff side of head, throat and breast; upperparts grey-brown, rump with paler feather edges; wings and tail dark brown, tail almost square; abdomen and undertail-coverts white, underwing-coverts grey-brown. Differs from *Stelgidopteryx ruficollis* in tawny head, darker rump and smaller size. Sexes alike. Juvenile resembles adult, but head yellowish-fawn rather than tawny-rufous. Voice. A soft "treeb" uttered in flight.
Habitat. Open areas, especially grassland, particularly near water such as marshes, ponds and streams. Up to 1600 m.
Food and Feeding. Diet includes flies (Diptera), beetles (Coleoptera) and Hymenoptera. Forages in pairs or small groups, not usually with other hirundines; flight direct, often low over ground.
Breeding. Sept-Nov. Solitary or in small loose groups. Nest of dry grass and feathers, placed in chamber at end of burrow, 1 m or more long, in riverbank or ditch; not known if digs own burrow or uses or adapts existing one. Clutch 4-5 eggs, rarely 6, in Argentina; no information on incubation and fledging periods.
Movements. Migratory in S. Forms post-breeding flocks, sometimes large ones (one of over 100 individuals). Absent from S parts of range Apr-Jul; non-breeding distribution not well known, possibly in N part of main breeding range, but recorded as far N as Colombia and N Venezuela. In SE Brazil (Rio Grande do Sul), present all year but more common in austral winter, perhaps the result of seasonal immigration from S. Wanderers also recorded S of breeding range in Argentina (S to Río Negro), and in Falkland Is.
Status and Conservation. Not globally threatened. Generally uncommon or fairly common; rare in Peru. Limits of distribution not well known; possibly more widespread than currently realized. Apparently resident, and possibly breeds, in E Venezuela (Gran Sabana) and adjacent N Brazil (NE Roraima), as birds caught there were in breeding condition; further fieldwork required in that region. Restricted to areas with natural nest-sites, and rarely uses artificial ones.

46. **Barn Swallow**

Hirundo rustica

French: Hirondelle rustique **German**: Rauchschwalbe **Spanish**: Golondrina Común
Other common names: Swallow, Chimney/Common/House/Rustic Swallow; American Barn Swallow (*erythrogaster*); European/Eurasian Swallow (*rustica*); Nile/Egyptian Swallow (*savignii*)

Taxonomy. *Hirundo rustica* Linnaeus, 1758, Sweden.
Forms a superspecies with *H. lucida*, *H. angolensis*, *H. tahitica*, *H. neoxena*, *H. albigularis* and *H. aethiopica*, at least some of which have sometimes been considered conspecific with present species. Taxonomy uncertain; races possibly constitute two or more species, with sister-taxa in North America and Siberia. American race *erythrogaster* most resembles E Asian forms in colour and breastband pattern, but mitochondrial-DNA studies, combined with behaviour, suggest that it may be a separate species from that in Old World; proposed race *insularis*, from islands in N Gulf of Mexico, considered inseparable from mainland breeders. Populations in Eurasia intergrade; *mandschurica* often included in *saturata*, which itself is often subsumed in *gutturalis* or *tytleri*; birds from N India (Sikkim), originally described as separate race *ambigua*, probably belong in *gutturalis*, although sometimes included in nominate. In addition, clinal variation apparent: tail length decreases from N to S, and in Eurasia size decreases from NW & NE to S & E. Hybridizes with *Petrochelidon pyrrhonota* and *P. fulva* in America, and with *Delichon urbicum* in Europe and Asia. Eight subspecies tentatively recognized.

Subspecies and Distribution.
H. r. erythrogaster Boddaert, 1783 - breeds North America from S Alaska and W & S Canada (S from S Yukon, CW Mackenzie, N Saskatchewan, N Manitoba, N Ontario, SC Quebec and S Newfoundland) S through most of USA (except extreme SW, also S Florida) to Mexico (NW Baja California, and interior S to Colima, Michoacán and Puebla); also South America in E Argentina (N Buenos Aires). Winters from Pacific slope of C Mexico and W Panama, and E West Indies (Puerto Rico, Lesser Antilles), S through most of South America.
H. r. rustica Linnaeus, 1758 - Europe and W Asia from Ireland, Britain and N Scandinavia E to C Russia (E to R Yenisey), W Mongolia and W China, S to Mediterranean, N Africa (E to Libya), Iraq and C Himalayas; winters mainly sub-Saharan Africa, also S Asia.
H. r. savignii Stephens, 1817 - Egypt (Nile Valley).
H. r. transitiva (Hartert, 1910) - Lebanon, Syria, Israel and W Jordan.
H. r. tytleri Jerdon, 1864 - SC Siberia (R Yenisey E to Yakutskaya) S to N Inner Mongolia; winters E India and SE Asia.
H. r. saturata Ridgway, 1883 - E Russia (Kamchatka and Sea of Okhotsk coast S to mid-Amur Basin); winters SE Asia.
H. r. mandschurica Meise, 1934 - NE China; winters SE Asia.
H. r. gutturalis Scopoli, 1786 - E Himalayas, S, C & E China, Korea and lower R Amur E to Kuril Is, Japan and Taiwan, also possibly irregularly in Kamchatka; winters S & SE Asia S to N Australia.

Descriptive notes. 18 cm; 16-24 g. Distinctive plumage pattern and long tail-streamers. Male nominate race has forehead rufous-chestnut, crown and upperparts glossy steel-blue; wings and tail black, white patches on inner webs of rectrices (except innermost pair), outer tail feathers greatly elongated; throat rufous-chestnut, broad steel-blue breastband; rest of underparts, including undertail-coverts and underwing-coverts, creamy or buffy white. Female is less glossy, with shorter tail-streamers. Juvenile is duller, forehead and throat paler, short tail. Races differ in size, extent of breastband (narrower in Asian races), and colour of underparts (but underpart colour also varies individually within a population, and, within pairs, females tend to be paler below than mates): *savignii* has underparts rufous-chestnut; *transitiva* has underparts rufous-buff; *tytleri* has underparts rufous-chestnut; *saturata* is rusty-ochre below; *mandschurica* differs from previous in having paler ochre underparts; *gutturalis* has creamy white underparts; *erythrogaster* has throat more extensively rufous, blue band reduced to patch on each side of breast, underparts rufous-chestnut to orange. Voice. Song is a rapid twittering often ending in a harsh rattle; main contact call is "witt-witt", often repeated to form a twitter and uttered in flight or at nest; females also have own contact call, "tir-huit"; parents call when landing at nest to feed chicks; males use a "wi-wi-wi" call to attract females to nest-site and to entice chicks to leave nest; other calls include a courtship call "it-it-it", and a copulation call "waeae-waeae", and various alarm and distress calls such as the "chirr-chirr" directed at conspecifics and predators, a "tsi-wit" alarm call frequently uttered when a predator is close, a "dschiddschid" uttered in flight, a low pitched "flüh-flüh" when chased, a soft "dewihlik", and a sharp "weer-weer" when caught by a predator. American race *erythrogaster* has similar calls to nominate, including a twittering song, a chirping contact call, stuttering threat or anger calls, various alarm calls, a whistling call used to maintain pair-bond, a whining call during copulation and a "cheet" call used by parents feeding fledglings.

Habitat. Open country, cultivation, human habitations, often near water. In Europe and North America mainly a rural bird, with preference for breeding on farms with livestock (especially cattle) in N & C Europe; in N Africa and Asia, often breeds in busy towns and cities. From sea-level to c. 3000 m, usually below 1000 m in Europe. Forages over variety of open habitats, in adverse weather also often over waterbodies. On African wintering grounds usually near wetlands. Roosts mainly in reedbeds or other dense vegetation in or near water, tall grasses, crops, bushes or tree canopy; also on overhead wires in towns, and on or in buildings, especially in cold weather.

Food and Feeding. Diet varies within and between years and sites, depending on local availability of insects. More than 80 insect families recorded in diet: large dipteran flies, such as hoverflies (Syrphidae), horseflies (Tabanidae) and blowflies (Calliphoridae), important prey in breeding season, with more aphids and fewer large flies taken as season progresses; flying ants and termites (Isoptera) important in winter. In samples taken throughout North America, 40% of prey items were flies (Diptera), 23% Hymenoptera, 16% beetles (Coleoptera), 15% bugs (Hemiptera). In Scotland, 82% dipterans, 5% Hymenoptera, 12% beetles, with adult diet in early summer 69% dipterans, 1% Hymenoptera, 26% beetles. Nestling diet in Europe 43-76% dipterans, 1-5% Hymenoptera, 1-5% beetles, 9-28% hemipterans. On wintering grounds, 8% dipterans, 48% Hymenoptera and 37% coleopterans in Africa (Malawi), and 8% dipterans, 82% Hymenoptera and 6% coleopterans in Malaysia. The Hymenoptera taken are mostly ants and parasitic wasps, with few wasps and bees (mostly drones). Other arthropods in diet include psocids (Psocoptera), Odonata (mainly damselflies), Lepidoptera (adults, occasionally caterpillars), mayflies (Ephemeroptera), grasshoppers and crickets (Orthoptera), caddis flies (Trichoptera), lacewings (Neuroptera), earwigs (Dermaptera), amphipods and spiders (Araneae). In S Africa non-breeding migrants also eat arillate seeds of acacia trees (*Acacia*); a few records of berries being eaten. Feeds alone or in pairs in breeding season, mostly low down, on average 7 m (often less than 1 m) above ground or water. Forages at up to c. 600 m from nest, average distance 170 m. Flight straight and rapid, with frequent sharp turns to catch prey; infrequent, short glides. Sometimes take prey from ground, vegetation, water or other surfaces, while either perching or hovering, especially in adverse weather. Follows other animals and tractors to take insects flushed by them.

Breeding. Mainly May-Aug, starting later at higher latitudes (e.g. early Jun in Finland) and earlier in S (e.g. from Feb-Mar in N Africa); Nov-Mar in Argentina; when nesting in group, laying occurs over extended period; 1-3 broods (1-2 in North America), single-brood females lay later than those with multiple broods, and older females more likely than first-years to have two broods. Socially monogamous, occasionally polygynous; extra-pair paternity common, c. a third of nestlings in European studies, 22% in Canada (Ontario). Solitary or in groups of usually 2-30 pairs, but groups of up to 250 pairs recorded; average inter-nest distance in groups 3-5 m, but can be as little as 10-20 cm, especially when population density high; area of 4-25 m² around nest defended. Male attracts females to nest or site by displaying tail and singing, also communal singing displays while circling above breeding site; male sings to solicit copulation, which occurs on perches outside as well as near or in nest, also guards mate during nest-building and egg-laying. Both sexes build nest, a cup or half-cup c. 20 cm wide × 10 cm high, made from mud pellets mixed with fibres such as dry grass, straw and horsehair, lined with dry grass, then white feathers, construction usually takes 7-10 days, with additional few days for lining; female adds feathers during incubation and removes them as nestlings grow; nests often repaired and reused, with mud added to rim, can last for 12-15 years, occasionally up to 48 years; site originally in cave or cliff, sometimes in hollow tree, now almost always in or on artificial structure such as building, barn, bridge, culvert, well or mine shaft, and placed usually 2-5 m above ground or water on ledge or vertical wall close to an overhang; objects projecting from wall (such as a nail or a wasp nest) often used as a base. Clutch 2-7 eggs, usually 3-6, and 4 or 5 most common (e.g. of 177 clutches in Scotland, 34% were of 4 eggs, 51% of 5, 12% of 6, 3% of 2-3); size of second (but not of first) clutch increases with latitude (averages 4·07 in Iraq to 4·75 in Finland), also decline through season (e.g. in Spain first clutch 4·99, second 4·52, third 3·89); egg-dumping by conspecifics occurs (3% in a Spanish study, with nest-owner male sometimes the father); incubation by female alone in most races, in North America (*erythrogaster*) male does small and variable amount (average 9% in Ontario), bouts average 7-10 minutes, longer in cold weather, incubation period 13-16 days; eggs hatch mostly over 1 day (up to 3 days), chicks brooded at decreasing rate for 6-9 days, older chicks still brooded in bad weather and at night, fed by both sexes (male's contribution varies among pairs), feeding rate varies with brood size and age, weather conditions and time of season (e.g. in Scotland averages of 32·3 visits per hour for first broods, 26·5 for second broods), male brings smaller food boluses than female; young leave nest at c. 21 days (variable, 18-27 days), stay near site and away from other families, roost in nest, and fed by parents for c. 1 week, independent after 1-2 weeks. Average breeding success c. 70-90%, but can be reduced especially by prolonged bad weather and parasite infestations; annual productivity 0-16 fledglings per pair, average 4·2-7·1; nest competitors include *Petrochelidon pyrrhonota* and *Delichon urbicum*, effect usually minor, but House Sparrows (*Passer domesticus*) can have major impact; predation uncommon, but can be locally important cause of mortality; in one study, infanticide accounted for 32% of chick deaths over 5 years. Recorded longevity 15 years 11 months.

Movements. Mainly long-distance migrant. On breeding grounds mainly Apr-Oct; forms large post-breeding flocks and roosts, sometimes hundreds of thousands or millions of birds. Autumn migration is over a broader front than that in spring and takes several months; routes along coastlines or over land, e.g. many W European birds head for Iberian Peninsula and the Mediterranean. Those breeding in S Europe and N Africa leave Jul-Aug, but peak of migration in N & C Europe Sept/early Oct; arrives in N Africa in large numbers from mid-Sept to late Oct, and in S Africa in Nov, present in Africa mainly Sept-Apr, with some in Aug and May and a few in Jun and Jul. Different populations tend to migrate to different areas (but mix to some extent), N African and S European birds to W Africa, N & C European birds to S & SW Africa, but E birds tend to winter on E side and W birds on W side (E-W divide most marked in C Africa); also, individuals from particular areas tend to be recorded in particular parts of wintering range, e.g. British and Russian predominate in S Africa. Wintering areas sometimes change (British and Irish birds extended range, from E South Africa and S to E Cape Province, to farther S & W after 1961, following a drought); generally faithful to winter sites in subsequent years. Return migration to N & C European breeding grounds starts Jan-Mar, mainly Feb, and most have left by late Apr; peak passage in N Africa and Mediterranean mid-Mar to late Apr, and in NW Europe mid-Apr to mid-May; birds breeding in N Africa and S Europe arrive mainly Feb-Mar. Non-breeding range of North America populations extends from Pacific slope of C Mexico and W Panama, Puerto Rico and Lesser Antilles S to C Chile and N Argentina, rarely farther S; autumn departure in N relatively earlier than in Europe, e.g. late Aug to early Sept at Cape May (New Jersey) and in British Columbia; most travel down coastal lowlands of Middle America, some flying via the Gulf of Mexico and Caribbean, and first migrants in South America recorded Aug in Colombia, Surinam and French Guiana, early Sept in Brazil and Paraguay, late Sept in Argentina; main spring migration through Middle America in Mar-May, and in West Indies and Bermuda Apr-May; some also remain in South America during N summer. E Asian races (*tytleri*, *saturata*, *mandschurica*, *gutturalis*) make similar long-distance movements, migrating to S Asia, e.g. populations breeding in SE Siberia, Korea and Japan recorded in Thailand, Malaysia, Borneo and Philippines; winter range of *gutturalis* has extended S to N Australia during 20th century, with a few records also in E & S Africa. Migratory races also regularly recorded in winter in S parts of breeding range, e.g. Spain and N

On following pages: 47. Red-chested Swallow (*Hirundo lucida*); 48. Angolan Swallow (*Hirundo angolensis*); 49. Pacific Swallow (*Hirundo tahitica*); 50. Welcome Swallow (*Hirundo neoxena*); 51. White-throated Swallow (*Hirundo albigularis*); 52. Ethiopian Swallow (*Hirundo aethiopica*); 53. Wire-tailed Swallow (*Hirundo smithii*); 54. White-throated Blue Swallow (*Hirundo nigrita*); 55. Pied-winged Swallow (*Hirundo leucosoma*); 56. White-tailed Swallow (*Hirundo megaensis*); 57. Pearl-breasted Swallow (*Hirundo dimidiata*); 58. Montane Blue Swallow (*Hirundo atrocaerulea*); 59. Black-and-rufous Swallow (*Hirundo nigrorufa*).

Africa, E Mediterranean, S islands of Japan, and *erythrogaster* casually in C California, SW USA, N Mexico and S Florida. Timing of arrival on breeding grounds is related to prevailing temperature; also, older males arrive back first; adults normally return in subsequent seasons to same site (generally fewer than 5% change site), and often to same nest (in North American study, 65% returned to same or neighbouring nest). Egyptian *savignii* is resident; Middle East race *transitiva* probably migrates short distances, recorded in non-breeding season farther W (in Egypt) and unconfirmed (but doubtful) reports farther S. Widespread vagrant, e.g. N Alaska, St Lawrence I, Pribilof Is and Aleutian Is, Greenland, Jan Mayen, Bear I, Spitsbergen, Hawaiian Is, Falkland Is, South Georgia, Tristan da Cunha.

Status and Conservation. Not globally threatened. Generally very common and widespread, but marked declines in some areas. In terms of population size and range, has probably benefited greatly from increased nesting opportunities provided by human activities; is, however, vulnerable to periods of cold, wet weather on breeding grounds and drought in non-breeding quarters (especially Africa), and fluctuations in population size are common. In North America, decreased in NE USA in late 1800s, possibly because of introduced House Sparrows, which are serious nest-site competitors, taking over nests and destroying eggs and nestlings, but range expanded in latter half of 20th century owing to increased availability of nest-sites on new bridges, culverts and buildings in areas previously unsuitable (e.g. in California, Arkansas, Tennessee, Louisiana, Mississippi, Alabama). Between 1966 and 1994, population in North America increased in USA but decreased in Canada; spread in Florida by 1987, after first nesting in 1946, and increased in Carolinas, Georgia and S Mexico (Colima). First confirmed nesting in South America in 1980; restricted to N Buenos Aires, but indication of recent spread there. In Europe and Russia, total population c. 13,000,000-33,000,000 breeding pairs. Some local declines evident in UK; widespread decline of 20-50% occurred 1970-1990 in W & C Europe, and recent range contractions in some countries, including Spain and Austria; one Danish population showed mean decline of 7·6% per year during 1984-1999. Little direct impact of human activities on populations, although some hunting for food or sport occurs, and nests sometimes regarded as a nuisance and removed. Main threat has been intensification of agriculture with loss of suitable foraging areas, such as waterbodies and hedges, and reduction in insect abundance from pesticide use, as well as loss of nest-sites; in particular, a reduction in dairy farming has been associated with lower population abundance, reproductive success and nestling growth. Can be encouraged to nest by provision of wooden ledges or of artificial nest cups made of cement and sawdust or papier maché.

47. **Red-chested Swallow**

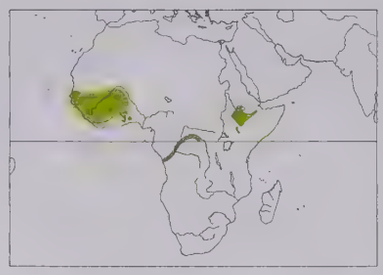
Hirundo lucida

French: Hirondelle de Guinée **German**: Singschwalbe **Spanish**: Golondrina de Guinea
Other common names: African (Barn) Swallow; Gambian (Barn) Swallow (*lucida*)

Taxonomy. *Hirundo lucida* Hartlaub, 1858, Casamance River, Senegal.

Forms a superspecies with *H. rustica*, *H. angolensis*, *H. tahitica*, *H. neoxena*, *H. albigularis* and *H. aethiopica*; has been considered conspecific with *H. rustica*. Paler birds from N part of range of nominate often separated as race *clara*, but variation probably clinal. Three subspecies recognized.

Subspecies and Distribution.



H. l. lucida Hartlaub, 1858 - Senegal and extreme S Mauritania E to SW Niger, S to Liberia, N Togo and Benin.

H. l. rothschildi Neumann, 1904 - Ethiopian Highlands.

H. l. subalaris Reichenow, 1905 - R Congo.

Descriptive notes. 15 cm; 12-14 g. Has forehead rufous-chestnut, crown and upperparts glossy steel-blue; wings and tail black, tail moderately forked, large white patches on inner webs of rectrices (except central pair); throat and upper breast rufous-chestnut, blue breastband narrower (sometimes broken) in centre, rest of underparts white; dusky underwing-coverts. Differs from *H. rustica* in thinner breastband, shorter tail with more white in it. Female has shorter tail than male. Juvenile is duller, with rufous areas paler, shorter tail. Race *rothschildi* is more violet-blue above; *subalaris* has rufous areas darker, more chestnut. VOICE. Song is a weak, but clear and loud, twittering.

Habitat. Open country, grassland, savanna, marshes, rivers and lakes, forest clearings and human habitations. Lowlands; 1800-2750 m in Ethiopia.

Food and Feeding. Diet includes termites (Isoptera). Feeds alone, in pairs or in small groups, sometimes flocks of 40 or more individuals, often with other hirundines; low or at moderate heights. Flight rapid, with frequent banking and turning, as that of *H. rustica*.

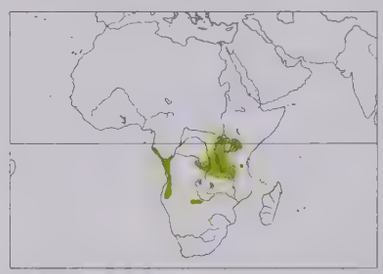
Breeding. Mar-Jul and Dec in Senegal, Mar-Jun in Gambia, Jul-Aug in Mauritania, Aug-Sept in Mali, Sept-Oct in Niger, and Mar-Apr, Jun-Aug and Dec in Togo; Feb-May and Aug-Sept in DRCongo; Apr-Jun, perhaps also Feb, in Ethiopia; may be double-brooded. Solitary or in small, loose groups. Nest an open cup made of mud pellets mixed with grass, lined with dry grass and feathers, placed on termite mound, rock, bridge, verandah, under eaves or, especially, in building, often on beam; nest sometimes reused. Clutch 3-4 eggs; no information on incubation and fledging periods.

Movements. Mainly resident. Movements occur in some parts of W Africa, e.g. in C Ghana, and S Benin in the rains; in Togo, in flocks in Jan-Apr but few in Sept-Dec. Recorded also in N Gabon. Vagrant in W Nigeria.

Status and Conservation. Not globally threatened. Uncommon to locally common, sometimes abundant. Readily uses bridges for nesting, and population may be increasing as a result.

Bibliography. Bannerman (1953), Barlow *et al.* (1997), Borrow & Demey (2001), Chapin (1953), Cheke & Walsh (1996), Christy & Clarke (1994), Dowsett (1989), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fishpool & Evans (2001), Gatter (1988, 1997), Gore (1990), Grimes (1987), Keith *et al.* (1992), Lamarche (1988), Lippens & Wille (1976), Mackworth-Praed & Grant (1973), Schepers *et al.* (1998), Urban & Brown (1971), Walsh *et al.* (1990).

48. **Angolan Swallow**



Hirundo angolensis

French: Hirondelle de l'Angola **German**: Angolaschwalbe **Spanish**: Golondrina Angoleña

Taxonomy. *Hirundo angolensis* Bocage, 1868, Huíla, Angola.

Forms a superspecies with *H. rustica*, *H. lucida*, *H. tahitica*, *H. neoxena*, *H. albigularis* and *H. aethiopica*; has been considered conspecific with *H. lucida*. E African birds described as race *arcticincta*, tending to be paler below and to have deeper tail-fork, but differences not constant and biometrics intergrade with those of adjacent populations. Monotypic.

Distribution. W Gabon, S PRCongo and W Angola; C, NE & E DRCongo, Uganda and W Kenya S to N & NW Zambia, N, W & E Tanzania and N Malawi; and NE Namibia (Caprivi Strip).

Descriptive notes. 15 cm; 16-19 g. Has forehead deep rufous-chestnut, crown and upperparts glossy steel-blue; wings and tail black, tail moderately forked, large white patches on inner webs of rectrices (except central pair); throat and upper breast deep rufous-chestnut, narrow blue breastband restricted or broken in centre, rest of underparts ashy-brown, undertail-coverts and underwing-coverts darker. Distinguished from *H. rustica* and *H. lucida* by brownish underparts. Female has shorter tail than male. Juvenile is duller, with rufous areas paler, short tail. VOICE. Song is a weak twittering.

Habitat. Open country, grassland, cultivation, swamp and forest edge, clearings, and human habitations. Mainly lowlands; to 2600 m in E Africa.

Food and Feeding. Diet includes flies (Diptera), mayflies (Ephemeroptera), Hymenoptera and beetles (Coleoptera). Feeds alone, in pairs or in small groups, at low or medium heights; flight slow compared with that of *H. rustica*.

Breeding. May and Sept in Gabon, May and Aug-Sept in Angola, Jan-Jul and Oct-Dec in Uganda, May in Kenya, Nov-Feb in Tanzania, Mar-May, Aug, Oct and Dec in DRCongo, May-Dec in Zambia and Oct-Dec in Malawi; may have up to three broods. Solitary or in groups (e.g. once c. 150 nests on building); 21 nests were up to 30 m apart. Nest an open cup made of mud pellets mixed with grass, lined with dry grass and feathers, placed 3·5-6 m above ground under overhang on bank, cliff, rock, in cave, on bridge, on verandah, or under eaves of building. Clutch 2-4 eggs, usually 3; incubation period 17-18 days; fledging period 22-27 days, usually 23 days; fledglings return to nest to roost for 3 weeks or more. In study in Uganda, 69% of eggs hatched, with 62% of eggs laid and 90% of eggs hatched producing fledglings (respective averages of 2 nestlings and 1·8 fledglings per nest); of 17 nests, four fledged no young.

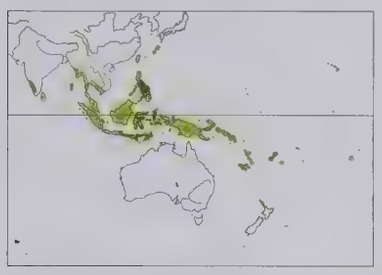
Movements. Mainly resident; migratory in some areas, e.g. mostly absent in Zambia Dec-Mar. Forms flocks of up to 500 after breeding.

Status and Conservation. Not globally threatened. Rare to locally common. Uncommon in W of range; in E, commoner W of Rift Valley than E of it, but locally common in E Tanzania. Nests mainly in natural sites, but may be increasing its use of artificial ones; range possibly expanded relatively recently N into Gabon.

Bibliography. Aspinwall (1982), Aspinwall & Beel (1998), Benson & Benson (1977), Benson *et al.* (1971), Bijnens & Upoki (1992), Borrow & Demey (2001), Britton (1980), Brown & Britton (1980), Butynski (1994), Byaruhanga *et al.* (2001), Dean (1974, 2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Friedman & Williams (1969), Ginn *et al.* (1989), Keith *et al.* (1992), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1960, 1963, 1973), Madge (1972), Newman (1996), Newman *et al.* (1992), Rand *et al.* (1959), Short *et al.* (1990), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).

49. **Pacific Swallow**

Hirundo tahitica



French: Hirondelle de Tahiti **German**: Südseeschwalbe **Spanish**: Golondrina del Pacífico
Other common names: House/Eastern/Coast Swallow; Eastern House Swallow (*tahitica*); Hill Swallow, Nilgiri House Swallow (*domicola*); Small House Swallow (*javanica*)

Taxonomy. *Hirundo tahitica* J. F. Gmelin, 1789, Tahiti.

Forms a superspecies with *H. rustica*, *H. lucida*, *H. angolensis*, *H. neoxena*, *H. albigularis* and *H. aethiopica*; sometimes treated as conspecific with *H. neoxena*, but differs morphologically (especially in bill size and in tail structure and markings). Sometimes split into two species, based on E "nominate group" (also including *ambiens* and *subfusca*) and paler W "*javanica* group", but racial variation is clinal throughout; the groups meet in W Melanesia, where birds in New Britain (*ambiens*) are intermediate between the two, and individuals on Long I (in S Bismarck Sea) appear intermediate between New Britain and N New Guinea populations. Further, race *domicola* has been considered a separate species by some, in part because of its geographical isolation from other races and its greenish, rather than blue, gloss; taxonomic status requires review. Race *frontalis* not well differentiated, also has been thought to include individuals from Wallacea, but they probably belong with *javanica*; birds from Philippines and Borneo (and sometimes those W to Malay Peninsula and S to Sumatra) intergrade with latter, and generally indistinguishable from it, but sometimes treated as a separate race *abbotti* (with which *mallopega* from N Philippines synonymized). Eight subspecies recognized.

Subspecies and Distribution.

H. t. domicola Jerdon, 1844 - S India and Sri Lanka.
H. t. javanica Sparrman, 1789 - Andaman Is, and from coastal Myanmar, S Thailand, S Cambodia and Cochinchina S to Sundas and Wallacea and E to Philippines.
H. t. namiyei (Stejneger, 1887) - Ryukyu Is (Nansei-shoto) and Taiwan.
H. t. frontalis Quoy & Gaimard, 1830 - N & W New Guinea.
H. t. albescens Schodde & Mason, 1999 - S & E New Guinea.
H. t. ambiens Mayr, 1934 - New Britain, in Bismarck Archipelago.
H. t. subfusca Gould, 1856 - New Ireland E through Solomons, New Caledonia and Vanuatu to Fiji and Tonga.
H. t. tahitica J. F. Gmelin, 1789 - Society Is (Moorea, Tahiti).

Descriptive notes. 13 cm; 11-16 g. Nominate race has forehead rufous-chestnut, crown and upperparts glossy steel-blue; wings and tail brownish-black, tail slightly forked, pale margins on inner webs of rectrices (except inner two pairs); throat rufous-chestnut, rest of underparts brownish-black, undertail-coverts grey-brown with dark subterminal band and pale tips. Distinguished from *H. neoxena* by darker underparts, pale margins (not spots) on rectrices, shorter outer tail feathers; from *H. rustica* by darker underparts, lack of breast-band, shorter tail. Sexes alike. Juvenile is duller, rufous areas paler, short tail. Races differ in shade of underparts, colour of upperparts and amount of white in tail, E races dark below with no tail spots, W races pale with white spots on inner webs of rectrices: *domicola* has green gloss above, ash-grey below, with white tail spots; *javanica* is purple-blue above, pale ash-brown with dark streaks below, large tail spots; *namiyei* is blue above, smoky brown below, with tail spots; *frontalis* differs from previous in being blue-black above, more grey below; *albescens* is paler ventrally, with larger tail spots; *ambiens* is blue above, grey below, tail spots small or absent; *subfusca* is blue above, grey-brown below with dark brown feathers on centre of breast, no tail spots. Voice. Twittering song "twsit-twsit-twsit"; also a "titswee".

Habitat. Sea coasts, open country, forested hills, and human habitations, especially near water; from sea-level to 2400 m. Feeds over grassland, cultivation, forest rivers and roads.

Food and Feeding. Diet in Malaysia 60% Hymenoptera (mainly flying ants and Apocrita), also flies (Diptera), beetles (Coleoptera) and termites (Isoptera); took larger insects than did *H. rustica* in same area; fewer ants taken in Mar-Apr, and more large flies in May. Forages alone or in groups, of usually up to five individuals; at low levels, average height 11 m in forested areas, 14 m in open areas, often within 10 m of vegetation. Flight fast, with frequent turns and short glides.

Breeding. Mar-May in India, mainly Feb-May in Sri Lanka; Mar-May in Myanmar, Jan-Aug in Malay Peninsula; Jan-May in Ryukyu Is, Mar-May, Jul and Oct in Philippines, and mainly Dec-Jul in Borneo; Nov and Dec in Tahiti; often two broods (29% of pairs in Malaysian study). Solitary or in small loose groups, 1 m or more between nests; group of 35 pairs recorded in Malaysia and up to 40 in Ryukyus and Tahiti. Nest built by both sexes, a half-cup made of mud pellets, lined with dry grass, rootlets, lichens and feathers; close to overhang, often over water, on cliff, in cave, on tree stump, culvert, bridge, jetty or verandah, under eaves, or on rafter inside building; nest repaired and reused in successive years. Clutch 2-3 eggs in India, usually 3 (2-4) in Sri Lanka, average 3 in Malaysia (clutch size decreases during season), 3 in Philippines, 2-4 in Borneo and 1-2 in Tahiti; incubation by female (although male *domicola* reported to help), period 15-17 days, generally 16; chicks fed by both sexes, feeding rates highest in late morning and at dusk; fledging period c. 20 days, range 17-22 days; young return to nest at night for several days. Breeding success 38% in Malaysian study, with 54% hatching success. Recorded longevity 7 years.

Movements. Mainly resident; post-breeding movement to lower altitudes in India and Sri Lanka (*domicola*), and in Ryukyus (*namiyei*) may move between islands after breeding. Transients reported, e.g. from Lanyu I and Huoshao Tao (off Taiwan). Joins flocks with other hirundines after breeding.

Status and Conservation. Not globally threatened. Generally common, though typically rather local. Common in SE Asia and in Philippines. Often limited to cliffs along coast, but has taken advantage of artificial nest-sites, such as at hill stations in Malaysia, resulting in some range expansion to inland areas.

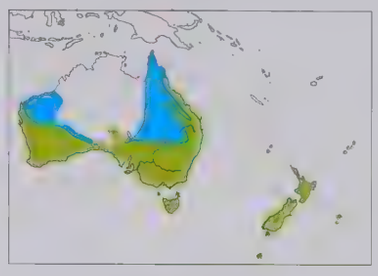
50. Welcome Swallow

Hirundo neoxena



French: Hirondelle messagère **German**: Glücksschwalbe **Spanish**: Golondrina Australiana

Taxonomy. *Hirundo neoxena* Gould, 1843, Tasmania.

Forms a superspecies with *H. rustica*, *H. lucida*, *H. angolensis*, *H. tahitica*, *H. albigularis* and *H. aethiopica*; sometimes treated as conspecific with *H. tahitica*, but differs morphologically (especially in bill size and in tail structure and markings). Races poorly defined; tail length increases slightly from SE Australia W to Eyre Peninsula and decreases in W Australia, more so in males than in females. Proposed race *parsonsi* from NE Australia (E Queensland), supposedly with less white in tail, considered indistinguishable. Two subspecies recognized.

Subspecies and Distribution.

H. n. carteri (Mathews, 1912) - W Australia.
H. n. neoxena Gould, 1843 - SC & E Australia, Tasmania, Lord Howe I, Norfolk I, New Zealand (including Great Barrier I), Kermadec Is, Chatham Is and Auckland Is.

Descriptive notes. 13-17 cm; 12-17 g. Has forehead rufous-chestnut, crown and upperparts glossy steel-blue; wings and tail blackish-brown, tail deeply forked, white patch on inner webs of rectrices (except central pair); throat and upper breast rufous-chestnut, rest of underparts greyish-white, brown tinge on sides and underwing-coverts; undertail-coverts grey-brown, dark subterminally, with pale edges. Distinguished from *H. tahitica* by paler underparts, pale spots (rather than margins) on rectrices, longer outer tail feathers; from *H. rustica* by lack of blue band below throat. Female has shorter tail than male. Juvenile is duller and browner, rufous areas paler, tail shorter. Race *carteri* differs from nominate only in larger size. Voice. Song is a mixture of twittering and trills; contact call "seet" and a sharp alarm call "twsee", "sweert" or "tit-swee".

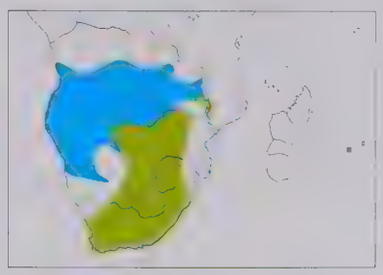
Habitat. Open country, coasts, cultivation and human habitations, often near water. Roosts in wetlands.

Food and Feeding. Diet includes flies (Diptera), Hymenoptera, beetles (Coleoptera), bugs (both heteropterans and homopterans), stoneflies (Plecoptera), Odonata, caddis flies (Trichoptera), Lepidoptera and springtails (Collembola). Forages alone or in small groups, low over ground; flight fast, with frequent turns. Follows other animals to take insects flushed by them. Recorded as feeding at night on moths attracted to lights, and on flies inside a building.

Breeding. Jul-Apr, peak Sept-Oct, earlier inland than on coast; Aug-Feb in New Zealand; 2-3 broods. Solitary, sometimes in loose groups, with nests 0·1-1 m apart in one study; records of 20-25 nests under jetty and 500 birds in deserted farmhouse; aggressive towards intruders. Male fans tail during courtship displays, follows female during nest-building; may copulate on perch near nest. Nest constructed by both sexes, taking 6-24 days, most activity in morning, a half-cup made of mud pellets mixed with grass, lined with dry grass, rootlets, hair, wool and feathers, sometimes feathers added during incubation; placed on vertical surface close to overhang, 0·3-7·6 m (average 2·6 m) above ground or 0·3-12 m (average 1·72 m) above water, mostly in artificial site such as culvert, bridge, jetty, mine shaft, water tank, verandah, rafter inside building or on wall or under eaves, usually on outside of building, less often on cliff, in cave or in hollow tree; also recorded on other sites such as moving boat, mailbox, *Petrochelidon ariel* nest; old nests repaired and reused. Clutch 2-7 eggs, usually 4 or 5; clutch size averaged 4·5 in New Zealand, 3·9 in Australia (of 380 Australian clutches, 61·3% were of 4 eggs, 17·9% of 3, 16·8% of 5, and 4% of 6, 2 or 1, the last possibly reduced by predation); incubation by female, but male has been recorded on eggs, and also, rarely, male seen to bring food to incubating mate, period 14-19 days, in one study average 15·6 days; eggs hatch mostly over 1-2 days, chicks fed by both sexes, rate 17-24 feeds per hour at a nest with four chicks; fledging period 18-23 days (average 20·6), longer in New Zealand (average 21·5 days) than in Australia (average 18·9); young fed near nest, and return to it to roost for a few days, sometimes up to c. 3 weeks, in one case while second clutch was laid and incubated. Average fledging success 74% and breeding success 53%; losses of eggs and chicks caused mainly by bad weather, nest competition from sparrows (*Passer*), predation, nest falls and disturbance. Oldest bird 6 years.

Movements. Resident and partial migrant; forms flocks after breeding, usually of up to 500 birds. Resident or partial migrant in W Australia and New Zealand; passage movements occur, e.g. in coastal Otago (S New Zealand), and flocks recorded outside breeding range, and in areas with few breeding birds, in non-breeding season, e.g. in Southland (S New Zealand). Partially migratory in E Australia; non-breeding visitor in N Australia, including Torres Strait, but also present in S, including Tasmania, in austral winter. Main passage movement Feb-Mar and Aug-Sept. Adults will return to same site to breed in successive years. Recent records also from New Guinea and New Caledonia and from other island groups.

Status and Conservation. Not globally threatened. Common. Has extended range outside Australia since late 1950s. First recorded in New Zealand in 1958, in Northland, and present throughout Northland by 1965; numbers and range have increased, both on South I and North I and on islands offshore. Expansion possibly continuing; non-breeding individuals also recorded in last few decades in New Guinea and New Caledonia, as well as on other island groups. Has benefited from presence of artificial nest-sites. Spread in breeding distribution appears to have followed expansion of farmland.



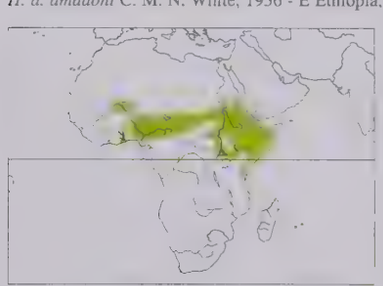
Bibliography. Ashton, C.B. (1986), Ashton, J.C. (2000), Ashton, J.C. & Armstrong (2002), Bailey & Sorensen (1962), Bishop & Bishop (1985), Blakers *et al.* (1984), Brock (1978), Broun & Broun (1970), Brown *et al.* (1990), Bull *et al.* (1985), Burbidge (1984), Campbell (1901), Chambers (2000), Child (1982), Claridge (1983), Coates (1990), Cowan (1968, 1971), Craig (1984), Crouchley & Crouchley (1979), Denninson (1974), Disney (1988, 1991), Drake (1985), Edgar (1962, 1966), Evans *et al.* (2003), Falla *et al.* (1981), Finch (1980, 1984), Findlay *et al.* (1960), Flux & Wilson (1965), Gregory (1978), Hall & Sibson (1960), Hamilton (1981), Hankins (1963), Heather (1956), Heather & Robertson (1997), Henderson (1964), Hermes (1985), Hobbs (1966), Hollay (1971), Hughes (1973), Jenkins (1978), Kinsky (1970), Klapste & Klapste (1985), Latham (1981), Lovegrove (1970), Macdonald (1988), Marchant & Fullagar (1983), McKnight & McKnight (1991), Michie (1959a, 1959b), Moon (1992), Moon & Lockley (1982), Morcombe (2000), Morrison (1987), Munro (1969, 1973), Norris (1968), Park (1981a, 1981b), Pizzey & Knight (1997), Reilly *et al.* (1975), Robertson (1985), Ross (1962), Ross & Shanks (1960), Salter (1960), Sansom (1954), Saunders & de Rebeira (1985), Scarlett (1968), Schodde & Mason (1999), Schodde *et al.* (1983), Schrader (1976), Semmens (1993), Serventy (1958), Serventy & Whittell (1962), Simpson & Day (1998), Skegg (1962), Slater *et al.* (1989), Soper (1976), Storr (1965), Syms (1978), Tarburton (1986, 1993), Thomas (1966), Tunnicliffe (1968), Turbott (1965), Watson (1955), Watts (1999), Wood (1973), Wright (1964).

51. White-throated Swallow

Hirundo albigularis

French: Hirondelle à gorge blanche **Spanish**: Golondrina Gorgiblanca
German: Weißkehlschwalbe

Taxonomy. *Hirundo albigularis* Strickland, 1849, Cape Peninsula, South Africa.
Forms a superspecies with *H. rustica*, *H. lucida*, *H. angolensis*, *H. tahitica*, *H. neoxena* and *H. aethiopica*. Birds in N of range sometimes separated as race *ambigua* on basis of smaller wings and tail, but variation clinal. Monotypic.
Distribution. Botswana and Zimbabwe E to S Malawi and S to S South Africa (except NW); has bred Zambia and Namibia (possibly regular); single breeding report from C Angola requires confirmation. In non-breeding season also N to NC Angola and SE DRCongo and W to Namibian coast.



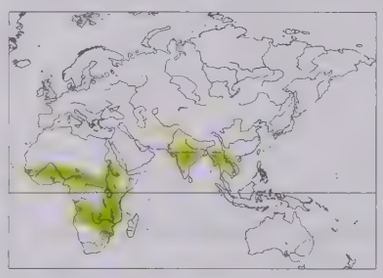
Descriptive notes. 14-17 cm; 16-29 g. Has rufous-chestnut forehead, glossy steel-blue crown and upperparts; wings brownish-black; tail blue-black, deeply forked, white patch on inner webs of rectrices (except central pair); underparts greyish-white, pure white on throat, with steel-blue breastband which tapers in centre; underwing-coverts white. Distinguished from similar *H. rustica*, *H. lucida* and *H. angolensis* by white throat, from *H. dimidiata* by breastband and chestnut forehead. Female has shorter tail than male. Juvenile is duller, with paler forehead and brown breastband. Voice. Song is a rapid twittering; calls include a sharp "chit" and nasal and squeaking notes.
Habitat. Grassland, open woodland, floodplains and human habitations, often near water.
Food and Feeding. Diet includes flies (Diptera), beetles (Coleoptera) and Hymenoptera. Forages alone, in pairs or in small groups, often low over the ground; mixes with other swallows. Flight rapid, with frequent banking and turning. Will hawk for insects from a perch and feed around other animals; occasionally feeds from ground.
Breeding. Generally Aug/Sept-Apr, with peak Oct-Dec; may have two or more broods. Solitary. Nest an open cup made of mud pellets, lined with rootlets, hair, dry grass and feathers, usually affixed under overhang, often above water, on rock face, culvert, dam, water tank, under bridge, on verandah, beneath eaves or ceiling, or in outbuilding; sites reused, but subsequent broods often reared in different nest. Clutch 2-5 eggs, normally 3; incubation 15-16 days; chicks fed by both sexes, fledging period 20-21 days; young return to nest for 12 or more days. Oldest bird 9 years 11 months.
Movements. Mostly migratory. Forms post-breeding flocks of up to 1000 individuals. Most migrate to areas N of R Zambezi, where present mainly from late May/early Jun to late Sept/Oct; returns to same nest-site. Mainly a passage migrant in Botswana, with peaks of movement Aug-Oct and Mar-Apr. Recorded in non-breeding season throughout range, most frequently in N, e.g. Zimbabwe. Vagrants recorded in N PRCongo and N Tanzania; report from Cameroon considered unacceptable.
Status and Conservation. Not globally threatened. Generally common, but local; in South Africa most abundant in wet E areas and in SW Cape. Marginal in Mozambique; breeds in Chimanimani Mts on border with Zimbabwe (but no recent records on Mozambique side), and reported from extreme W of Tete province probably as a passage migrant; earlier records from near Beira considered dubious. Extent of breeding distribution unclear, requires further study. Readily nests on bridges and dams, and probably extended its range during 20th century.
Bibliography. Aspinwall (1979b), Aspinwall & Beel (1998), Benson & Benson (1977), Benson *et al.* (1971), Borrow & Demey (2001), Britton (1980), Clancey (1964b, 1996), Dean (2000), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Earlé (1987d, 1988b), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Hockey (1996), Hockey *et al.* (1989), Irwin (1981), Jackson (1973), Jensen (1962), Keith *et al.* (1992), Lippens & Wille (1976), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993a), Medland (1989b, 1989c), Newman (1996), Newman *et al.* (1992), Oatley (2003), Penry (1994), Pollard (2001), Short *et al.* (1990), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Stevenson & Fanshawe (2002), Tarboton (2001), Tyler & Borello (1998), Vernon & Dean (1988), Zimmerman *et al.* (1996).

52. Ethiopian Swallow

Hirundo aethiopica

French: Hirondelle d'Éthiopie **German**: Fahlkehlschwalbe **Spanish**: Golondrina Etiópica

Taxonomy. *Hirundo aethiopica* Blanford, 1869, Barakit, Tigray, north Ethiopia.
Forms a superspecies with *H. rustica*, *H. lucida*, *H. angolensis*, *H. tahitica*, *H. neoxena* and *H. albigularis*. Birds from W Africa E to Sudan sometimes separated as race *fulvipectus* on basis of more buffy throat and breast, but probably indistinguishable from nominate. Two subspecies recognized.
Subspecies and Distribution.
H. a. aethiopica Blanford, 1869 - Senegambia, Guinea, Ivory Coast, Ghana, Togo, Benin, and from E Mali, N Burkina Faso, S Niger and C Chad S to N Cameroon and N Central African Republic and E to C & SE Sudan, W Ethiopia, N Uganda, N & SE Kenya and NE Tanzania.
H. a. amadoni C. M. N. White, 1956 - E Ethiopia, Somalia and NE Kenya.



Descriptive notes. 13 cm; 10-17 g. Nominate race has forehead rufous-chestnut, crown and upperparts glossy steel-blue; wings black; tail blue-black, deeply forked, with small white patches on inner webs of feathers (except central pair); throat and upper breast buffy white, incomplete steel-blue breastband, rest of underparts white to whitish. Differs from *H. lucida* in paler throat and breast. Sexes alike. Juvenile is duller and browner than adult. Race *amadoni* has whiter throat and breast. Voice. Song is a melodious twittering; calls are "cheep-cheep", "chip" and "cheut".
Habitat. Variety of open areas, including arid savanna and other grassland, open woodland, forest clearings, coastal cliffs; also human habitations, including towns. Lowlands and higher, to c. 2700 m in Ethiopia.
Food and Feeding. Diet includes flies (Diptera), Hymenoptera (including bees and flying ants), termites (Isoptera) and cicadas (Cicadidae). Feeds in pairs or small groups, often very low over ground; flight fast, with few glides. Will take non-flying insects from walls.
Breeding. Mar, Jul-Aug and Dec-Jan in Senegambia, Dec-Jan in Guinea, Apr-Jun in Ghana, Aug in Benin and Niger, Mar-Aug in Nigeria, Jul-Nov in Chad, Mar-Jul in Sudan, Apr-Oct in Ethiopia; mainly Mar-Jun and Dec in E Africa; may have two broods, occasionally three. Solitary or in loose groups. Nest built by both sexes, taking c. 2 weeks, an open cup made of mud pellets and dry grass and rootlets, lined with dry grass, rootlets, hair and feathers (coconut and palm-leaf fibres also recorded), sometimes nest of other swallow or of swift (Apodidae) used as base; affixed below e.g. eaves, overhang or beam, or (rarely) supported from below, on or in hut, house, stable, verandah or other building, or on bridge, less often in cave or coral overhang; nests reused. Clutch 2-4 eggs, usually 3; incubation probably mostly by female, c. 14 days; chicks fed by both sexes, fledging 25 days; young roost in or near nest for further week. Some nestling mortality from disease and/or parasites. Oldest recorded bird 7 years.
Movements. Mainly resident, but migratory or partially migratory in some areas. Forms post-breeding flocks of up to 500 individuals, roosts of up to 3000. Some resident in Ghana, with influx in rains; present in rains in Mar-Jul in N Ghana, Feb-Nov in SE Nigeria, May-Jul in Sudan; absent in Chad in Dec-Mar dry season. Mainly resident in E Africa; most abundant in Apr-May in Ethiopia. Vagrant in Israel.
Status and Conservation. Not globally threatened. Generally widespread, common and locally abundant; especially numerous in and around towns. Range has been expanding W in W Africa and S in E Africa since latter part of 20th century; scarce in Kenya and unknown in Uganda in early 20th century. Extension facilitated by its frequent use of artificial nest-sites. Suffers nest-site competition from Little and White-rumped Swifts (*Apus affinis* and *A. caffer*) and from *Cecropis abyssinica*.
Bibliography. Archer & Godman (1937-1961), Ash & Miskell (1998), Bannerman (1939, 1953), Bear (1991), Borrow & Demey (2001), Britton (1980), Brown & Britton (1980), Byaruhanga *et al.* (2001), Cheke & Walsh (1996), Clarke (1985), Demey & Fishpool (1991), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fishpool & Evans (2001), Grant & Lewis (1984), Grimes (1987), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1973), Morel & Morel (1990), Mulai (1999), Nikolaus (1987), Rydzewski (1978), Salvan (1969), Serle (1950a), Short *et al.* (1990), Stevenson & Fanshawe (2002), Thiollay (1985), Urban & Brown (1971), Zimmerman *et al.* (1996).

53. Wire-tailed Swallow

Hirundo smithii

French: Hirondelle à longs brins **German**: Rotkappenschwalbe **Spanish**: Golondrina Colilarga
Other common names: African Wire-tailed Swallow (*smithii*); Asian Wire-tailed Swallow (*filifera*)

Taxonomy. *Hirundo Smithii* Leach, 1818, Chisalla Island, Democratic Republic of Congo.
Sometimes considered to form a superspecies with *H. nigrita*, but substantial plumage and other morphological differences, combined with extent of range overlap in Africa (Congo Basin), make this unlikely. Two subspecies recognized.
Subspecies and Distribution.
H. s. smithii Leach, 1818 - sub-Saharan Africa from Senegal, S Mali and C Ivory Coast E to C & S Sudan, Ethiopia and Somalia, and S (outside C rainforest zone) to N Namibia, N Botswana and NE South Africa.
H. s. filifera Stephens, 1826 - S Uzbekistan, S Tadjikistan, Afghanistan, Pakistan, India, SW Nepal, Myanmar, N Thailand, Laos, Cambodia and C Vietnam.

Descriptive notes. 14-21 cm; 9-17 g. Distinctive. Has forehead and crown rufous-chestnut, upperparts glossy blue; wings and tail black with blue gloss, white patches on inner webs of rectrices (except central pair), outer tail feathers elongated to form thin filaments (difficult to see in the field); creamy white below, blue patch on each side of breast and on flanks. Female has shorter tail than male. Juvenile is duller, crown paler, tail shorter. Race *filifera* is larger than nominate. Voice. Twittering song "chirrickweet chirrickweet"; calls include a "chit-chit" uttered in flight and at a nest with young, a "chichip chichip" alarm call, and "twit", "pwee" and "che".
Habitat. Grassland, savanna, open woodland, clearings, cultivation, also human habitations, including towns; usually near water, such as lakes, rivers, canals and paddyfields. Mostly middle to low altitudes, below 2000 m, but up to c. 2700 m. Roosts in reedbeds and tamarisks (*Tamarix*).
Food and Feeding. Diet includes flies (Diptera), beetles (Coleoptera), bugs (Hemiptera), butterflies and moths (Lepidoptera), mayflies (Ephemeroptera), Hymenoptera and termites (Isoptera). Forages in pairs or small groups, mixes with other swallows and swifts (Apodidae). Feeds often low down (4-5 m high), and predominantly over water, but also over open ground and above trees. Flight fast. Occasionally perches on ground to take insects, and follows tractors and large animals.
Breeding. Generally two peaks, at start of rains, e.g. Jan-May and Jul-Dec in Senegal, all year (peaks Jan-Mar and Jul-Aug) in Gambia, Oct-May in Nigeria, Feb-Apr, Sept and Nov in Sudan, Jan, Mar-May and Aug-Nov in Ethiopia, all year (peaks Apr-May and Oct) in E Africa, Jun-Jul and Oct in Angola, Jan-Oct in Zambia, all months (peaks Mar and Sept-Oct) in Zimbabwe, mainly Mar-Apr and Sept-Oct in E South Africa, Apr-May and Oct-Nov in KwaZulu-Natal; Feb-Sept, varying locally, in Indian Subcontinent, and Jan-Nov in SE Asia; may have 2-3 broods. Solitary, occasionally a few pairs at same site but nests not usually clustered; aggressive towards other hirundines. Nest constructed by both sexes, taking c. 1 week, an open cup made of mud or of mud mixed with dry grass, lined with grass, rootlets and feathers, sometimes built on old nest of other swallow; 30 cm to 15 m above ground, usually affixed on wall, rafter, under overhang or close to a ceiling, in house, verandah, on culvert, bridge, pier, boathouse, boat, water tower, less often on cliff, in cave, on rock, or on tree overhanging water, and often along or near river, stream, lake, even irrigation channel or rice field; nests reused. Clutch 2-4 eggs (usually 3) in Africa, usually 3 in Pakistan, 3-5 in India, 3-4 in SE Asia; incubation by female, 13-19 days, mostly 14-15; chicks fed by both sexes, older ones more by female than by male, up to 16 feeds per hour, fledging period 15-24 days, usually 18-21 days; young return to nest for several days. Nests sometimes taken over by White-rumped Swift (*Apus caffer*). Oldest recorded bird 9 years 6 months.
Movements. In Africa, resident near nest-site in some areas, e.g. in Gambia, Central African Republic and W Nigeria, but absent in some months in E Nigeria, Benin, Burkina Faso, Ghana and Gabon; partial migrant, present mainly Mar/Apr-Oct, in C & S Africa, but some present all year and numbers vary seasonally. Occasionally reported farther afield, e.g. Egypt. In Asia, breeding visitor in N part of range, spending non-breeding season farther S; generally resident in S, but sometimes some local post-breeding movements. Recorded in NW & NE India, Bangladesh and Sri Lanka.
Status and Conservation. Not globally threatened. Varies from uncommon to locally abundant. Uncommon in W Africa, common and more widespread in E, common to locally very common in

S; common to uncommon and local in Indian Subcontinent; scarce to uncommon, locally more common, in SE Asia. The most numerous swallow in cultivated areas in much of range. Frequent use of artificial nest-sites, and construction of new bridges and buildings, have allowed it to spread during the last 100 years or so. Range has probably extended to W & SW in S Africa, and also on to Mashonaland Plateau and Chipinga Uplands in Zimbabwe; in W Africa, not recorded in Gambia until 1960s, but now regularly reported as breeding on artificial sites; expansion into Gabon and Cameroon probably also fairly recent. Some competition for artificial sites from House Sparrows (*Passer domesticus*).

54. White-throated Blue Swallow

Hirundo nigrita

French: Hirondelle à bavette **German**: Mohrenschwalbe **Spanish**: Golondrina Negrita
Other common names: Little Blue Swallow, West African/White-chinned Swallow

Taxonomy. *Hirundo nigrita* G. R. Gray, 1845, no locality = River Niger, West Africa.
Sometimes considered to form a superspecies with *H. smithii*, but substantial plumage and other morphological differences, combined with extent of range overlap in Africa (Congo Basin), make this unlikely. Monotypic.

Distribution. Sierra Leone, SE Guinea, Liberia, and S parts of Ivory Coast, Ghana, Benin and Nigeria, E to SW Central African Republic and DRCongo (except NE & SE) and S to NW & NE Angola (S to Cuanza Norte, Malanje and Lunda Sul); possibly also extreme W Uganda (R Semliki).

Descriptive notes. 12 cm; 15-22 g. Plumage is mostly glossy steel-blue with purple sheen, white patch on throat; wings black with purple gloss; tail almost square, black with blue gloss, white patches on inner webs of feathers (except central pair); blackish underwing-coverts. Sexes alike. Juvenile is duller and browner than adult. VOICE. Song is a weak twittering; calls include a "weetch", a "vwhit vwhit" and a soft "whit" uttered in flight.

Habitat. Rivers and streams in rainforest; also mangroves, harbours, land spits and lagoons.

Food and Feeding. Diet includes dipterans, especially horseflies (Tabanidae), also beetles (Coleoptera), Odonata, termites (Isoptera), Hymenoptera. Forages mostly in pairs, occasionally in small groups, once of over 40 individuals. Flight rapid, with frequent banking, occasional gliding. Sometimes hawks insects from riverbank perch or from rock or overhanging branch.

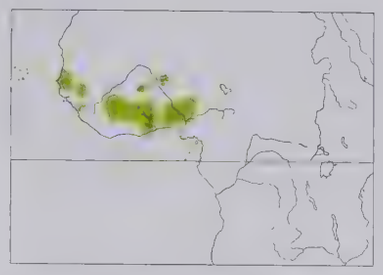
Breeding. Mainly in dry season, when river levels low: Mar in Sierra Leone, Oct-Mar in Liberia, Jan and Jun in Ghana, Jan-Feb and Aug in Nigeria, Jan-Feb and Jun in Cameroon, Jan-Mar and Jun-Aug in Gabon, Jan-Feb, Jul and Dec in DRCongo, and Mar-Apr and Aug in Angola; sometimes double-brooded. Solitary; aggressive towards intruders, pair keeps to limited area around nest-site. Nest built by both sexes, taking c. 3 weeks, an open cup made of mud pellets with some dry grass, lined with bark, grass and feathers, usually affixed under horizontal surface and generally 1-3 m (sometimes as little as 10 cm) above water and more than 5 m from riverbank, on rock, fallen tree or overhanging branch or cliff, but also recorded on artificial site such as bridge, pier, upturned canoe, or roof of house near water; nests sometimes reused. Clutch 2-3 eggs, rarely 4; incubation by female, 15 days or more; chicks fed by both sexes, fledge at 17-18 days; family-members stay together for a while.

Movements. Resident; possibly some local movements. Apparently present in Sierra Leone only Dec-Jul.

Status and Conservation. Not globally threatened. Locally common. Recorded density 1-2 nests/km of river. Recently recorded on Ugandan side of R Semliki, but not known if breeding there. Only occasionally exploits artificial nest-sites, but this habit (especially use of bridges) may be increasing.

Bibliography. Allport *et al.* (1989), Ash *et al.* (1991), Bannerman (1953), Borrow & Demey (2001), Brosset & Érard (1986), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Dean (1974, 2000), Dowsett (1989), Dowsett & Dowsett-Lemaire (1991, 1993, 1997), Dowsett & Forbes-Watson (1993), Dutson & Branscombe (1990), Fishpool & Evans (2001), Gartshore (1989), Gartshore *et al.* (1995), Gatter (1988, 1997), Germain *et al.* (1973), Grimes (1987), Harding & Harding (1982), Holman (1947), Keith *et al.* (1992), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1973), Prigogine (1980), Rand (1951), Serle (1949, 1950b, 1954), Stevenson & Fanshawe (2002), Thiollay (1985), Young (1946).

55. Pied-winged Swallow



Hirundo leucosoma

French: Hirondelle à ailes tachetées **Spanish**: Golondrina Alipinta
German: Scheckflügelschwalbe

Taxonomy. *Hirundo leucosoma* Swainson, 1837, West Africa.
In the past was sometimes placed with *H. megaensis* and *H. dimidiata* in a separate genus *Hemicecrops*, and has been thought by some authors to form a superspecies with those. Monotypic.

Distribution. Senegambia, N Guinea, NW Sierra Leone, S Mali, Burkina Faso, SW Niger, and N Ivory Coast and Ghana E to C Nigeria.

Descriptive notes. 12 cm. Distinctive. Has forehead to hindneck and upperparts glossy steel-blue, large white patches on inner greater upperwing-coverts, inner secondaries and tertials; tail slightly forked, black with blue-green gloss, white patches on inner webs of feathers (except central pair)

increasing in size outwards; throat and underparts white, blue patch on side of breast. Female has shorter tail than male. Juvenile is duller than adult, head browner, tail shorter. VOICE. Not very vocal; "chut" contact call.

Habitat. Wooded savanna, forest clearings and rivers; also around human habitations, including towns.

Food and Feeding. Details of diet not known. Feeds alone or in pairs, occasionally in small groups; also associates with other hirundines. Forages low down, over open grassland and around trees; flight buoyant and fast, with frequent turning and banking.

Breeding. Apr/May-Jun. Solitary. Nest built by both sexes, taking 15-30 days, a shallow open cup made of mud, lined with dry grass and other fibres; mainly on building and affixed to support such as projection from wall, rafter, or the junction of wall and roof, one nest 4·6 m down in a well, another 6 m up on a water tower; sometimes near *Cecropis semirufa*; nest reused in successive years. Clutch 4 eggs recorded; no other information.

Movements. May be resident with some post-breeding movements in some areas; partial migrant in others. In some areas recorded only (or mainly) during certain part of the year, e.g. Dec and Apr in Senegal, Nov-Apr in Niger, in rains in Ghana and N Nigeria, and Feb-Apr and Jul-Sept in Togo. Reported as vagrant in W Cameroon.

Status and Conservation. Not globally threatened. Generally scarce to uncommon, sometimes locally common. Distribution irregular. Has possibly benefited locally from its extensive use of buildings as nest-sites.

Bibliography. Bannerman (1939, 1953), Barlow *et al.* (1997), Borrow & Demey (2001), Cheke & Walsh (1996), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fishpool & Evans (2001), Fry (1980), Gore (1990), Grimes (1987), Holman (1947), Jensen & Kirkeby (1980), Keith *et al.* (1992), Louette (1981), Mackworth-Praed & Grant (1973), Morel & Morel (1990), Schepers *et al.* (1998), Traylor & Parelius (1967).

56. White-tailed Swallow

Hirundo megaensis

French: Hirondelle à queue blanche **Spanish**: Golondrina Coliblanca
German: Weißschwanzschwalbe

Taxonomy. *Hirundo megaensis* Benson, 1942, 10 miles [16 km] west of Mega, 4000 feet [c. 1220 m], Ethiopia.
In the past was sometimes placed with *H. leucosoma* and *H. dimidiata* in a separate genus *Hemicecrops*, and these three have been considered by some authors to form a superspecies. Monotypic.

Distribution. S Ethiopia (Yavello and Mega areas, in Sidamo Province).

Descriptive notes. 13 cm; 11 g. Male is glossy steel-blue above, wings black with blue sheen; tail slightly forked, inner feathers all white with black shaft streaks, outer feathers white on inner webs; throat and underparts white. Differs from *H. aethiopica* in blue (not rufous) forehead, whiter throat and breast without breastband, shorter tail with much more white. Female is less glossy than male, has shorter tail with less white. Juvenile is duller, with pale fringes on flight-feathers, tertials and uppertail-coverts and tail feathers. VOICE. Unknown.

Habitat. Open, semi-arid grassland with acacia (*Acacia*) bushes, also *Acacia* woodland, and villages. Mainly 1500-1700 m, sometimes down to 990 m and up to 2400 m.

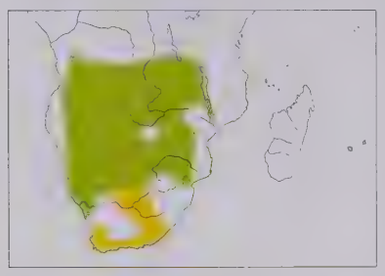
Food and Feeding. Diet includes beetles (Coleoptera). Forages around flowering trees; flight fast and elegant.

Breeding. Main rainy season in Apr-Jun, but suspected of breeding also in period Jan-Feb. Nest is an open cup, placed typically on roof pole in village hut or on wall of well, possibly also in termitarium and on culvert. One nest contained 3 eggs, and another held 4 chicks; no other information available.

Movements. Resident; possibly some local movements, as numbers vary.

Status and Conservation. VULNERABLE. Restricted-range species: present in South Ethiopian Highlands EBA. Population estimated to be in range 2500-10,000 individuals, but data poor. Although frequently seen, it occurs within small area of only c. 14,900 km^2. One survey in 1980s suggested a stable population, and another reported lower numbers but over a larger range; in a 1996 survey, found to be fairly common but occurring in small numbers. Threatened by clearance of vegetation for livestock grazing. Yavello Sanctuary was designated in 1985, in part to protect this species, but this reserve is not yet gazetted or managed. Conservation targets are to determine this hirundine's habitat requirements and the reasons why it has such a restricted range, and to ascertain the effects of scrub clearance on the population.

Bibliography. Ash & Gullick (1989), Benson (1942, 1946b), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Francis & Shirihai (1999), Hillman (1993), Holtam (1998), Keith *et al.* (1992), Mackworth-Praed & Grant (1960), Mohamued *et al.* (1992), Shirihai & Francis (1999), Shuker (1993), Stattersfield & Capper (2000), Syvertsen & Dellelegn (1991), Tilahun *et al.* (1996), Urban (1980), Urban & Brown (1971).



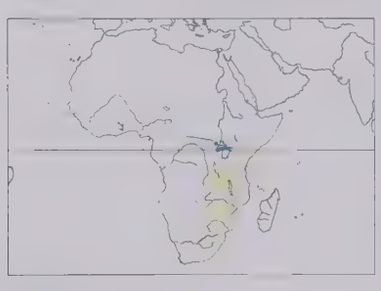
57. Pearl-breasted Swallow

Hirundo dimidiata

French: Hirondelle à gorge perlée **German**: Perlbrustschwalbe **Spanish**: Golondrina Perlada

Taxonomy. *Hirundo dimidiata* Sundevall, 1850, Leroma, Transvaal, South Africa.
In the past was sometimes placed with *H. leucosoma* and *H. megaensis* in a separate genus *Hemicecrops*, and has been thought by some authors to form a superspecies with those. Races poorly differentiated. Two subspecies recognized.

Subspecies and Distribution.
H. d. marwitzi Reichenow, 1903 - Angola, S DRCongo, Zambia, Malawi, Zimbabwe, NE South Africa and W Mozambique.
H. d. dimidiata Sundevall, 1850 - Namibia and Botswana S to the Cape.

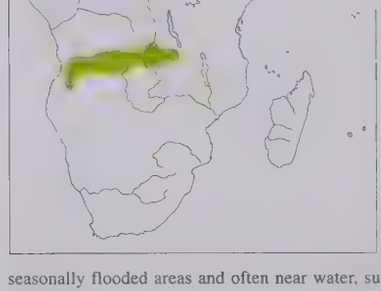


Descriptive notes. 13 cm; 10-15 g. Male is glossy blue above, wings blackish with slight blue gloss; tail slightly forked, blackish, usually without any white; grey-white below, grey wash on breast, dark tips of undertail-coverts. Distinguished from *Delichon urbicum* and *Pseudhirundo griseopyga* by lack of pale rump. Female has shorter tail and greener gloss than male. Juvenile is duller, with white tips to inner secondaries, shorter tail. Race *marwitzi* is smaller and darker than nominate. VOICE. Song is a harsh "chip-cheree-chip-chip"; also a courtship call "kss-kss", "twit" calls uttered in flight and a "chik", "chut" and "chuchut".
Habitat. Grassland, scrub, broadleaf woodland, miombo woodland edge and clearings, cultivation, and human habitations, often near water; also seen over swampy ground.
Food and Feeding. Details of diet not known. Forages alone, in pairs or in small groups, occasionally in flocks of up to 100. Feeds, probably on flies, around livestock and other animals; flies fast, often low down. Often perches on ground or stones.
Breeding. Aug-Oct in DRCongo, Aug-Sept in Zambia and Malawi, Sept in Mozambique, Oct-Jan in Namibia, Aug-Feb in Zimbabwe; Aug-Mar (mainly Aug-Oct) in E South Africa, but Aug-Apr (peak Oct-Dec) in the Cape; usually two broods, sometimes three in S. Solitary; occasionally in small groups in DRCongo. Nest built by both sexes, mainly male, over 3-4 weeks, an open bowl made of mud pellets and grass, lined with grass, hair, rootlets and feathers; affixed to wall or beam near roof of usually uninhabited building (especially hut with thatched roof, barn, poultry house), or on culvert, in mine or well, on rock, or in aardvark (*Orycteropus afer*) or porcupine (*Hystrix africaeaustralis*) burrow; nest of *Cecropis cucullata* sometimes used; nest reused for second brood, also in successive years. Clutch 2-4 eggs, usually 2-3, and one of 6 eggs reported; incubation by female, period 16-17 days; female also broods nestlings for at least 7 days, both sexes feed chicks, fledging period 20-23 days; young return to nest for several nights, fed by parents for a further 20 days.
Movements. Mainly resident with some post-breeding movement in N. Migratory S of c. 26° S; details not clear, but apparent influx in non-breeding season (mainly May-Jul) into N Botswana, Zimbabwe, Zambia and DRCongo. A few records from SW Tanzania, but uncertain whether these involve non-breeding migrants or a small breeding population.
Status and Conservation. Not globally threatened. Usually scarce and sparsely distributed, but can be locally common. Occurs throughout the year in Botswana but breeding not recorded there. Since 1900, numbers have increased in the Cape but decreased in Zimbabwe. Will use artificial nest-sites but, when it does, seems to prefer isolated, uninhabited buildings, and so has not benefited greatly from this habit; in South Africa, breeding on buildings largely restricted to W Cape. May suffer some competition for artificial sites from larger species; effects, if any, on population not known.
Bibliography. Aspinwall (1979c), Aspinwall & Beel (1998), Benson (1949), Benson & Benson (1977), Benson *et al.* (1971), Britton (1980), Claasen (1991), Clancey (1964b, 1996), Dean (1989c, 2000), Dean & Macdonald (1981), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Earlé (1988a), Every (1988), Fishpool & Evans (2001), Ginn *et al.* (1989), Harrison *et al.* (1997), Hockey (1996), Hockey *et al.* (1989), Irwin (1981), Keith *et al.* (1992), Lippens & Wille (1976), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993a), Medland (1989a, 1992a), Moyer (1983), Newman (1996), Newman *et al.* (1992), Pedersen (2000), Penry (1994), Priest (1935), Schmidt (1959), Short *et al.* (1990), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Spearpoint (1990), Stevenson & Fanshawe (2002), Tarboton (2001), Taylor (1983), Tree (1986b), Tyler & Borello (1998), Winterbottom (1962).

58. Montane Blue Swallow
Hirundo atrocaerulea

French: Hirondelle bleue **German**: Stahlschwalbe **Spanish**: Golondrina Azul
Other common names: (Eastern) Blue Swallow

Taxonomy. *Hirundo atrocaerulea* Sundevall, 1850, Natal, South Africa.
Has been placed in a separate genus *Natalornis* on basis of sexual dimorphism, distinctive plumage (without rufous, no white in tail), nest structure and egg coloration; within present genus, however, these features (apart from nest structure) are variable, suggesting that separate genus not warranted. Sometimes considered to form a superspecies with *H. nigrorufa*, but morphological differences probably too great to justify such a treatment. N population, with plumage washed violet, sometimes separated as race *lynesi*, but differences insignificant. Monotypic.
Distribution. Breeds SE DRCongo, S Tanzania, Malawi, NE Zambia, E Zimbabwe and adjacent W Mozambique, E South Africa (Eastern province and KwaZulu-Natal) and W Swaziland; migrates N to NE DRCongo, S Uganda and extreme W Kenya.



Descriptive notes. 18-25 cm; 13 g. Distinctive. Has glossy steel-blue plumage, sometimes with violet wash; outer tail feathers form very long, slender streamers; sometimes a few white streaks on flanks. Distinguished from *Psalidoprocne pristoptera*, the only similar all-dark swallow, by considerably longer tail. Female has shorter tail than male. Juvenile is duller, more sooty black, with brownish throat and chest, shorter tail, occasional white feathers on neck, rump and flanks. VOICE. Monotonous, plaintive song; calls include a quiet "choop-choop", a high-pitched alarm call, a quiet "chip chip" uttered in flight, and rapid "chip-pu-pu", "rip-rip" and "reap-reap".
Habitat. Open montane grassland; also seen in woodland edges and swamps. At 1500-2200 m in Zimbabwe, 850-1900 m in South Africa; at higher altitudes in N, e.g. 1800-2000 m in Tanzania.
Food and Feeding. Diet includes flies (Diptera). Feeds alone or in pairs, sometimes in groups of 4-5 individuals, occasionally up to 10; usually just above ground and working over a small area, but sometimes 50-100 m over valleys. Flight swift. Perches on bushes or stems, but flies almost continuously when breeding. Continues to forage in heavy mist; ceases during rain.
Breeding. Feb in DRCongo, Nov-Dec and Feb in Tanzania, Oct-Jan in Malawi, Nov-Jan in Zambia, Dec in Mozambique, Oct-Mar in Zimbabwe and South Africa; two broods reported, and two records of three at an artificial site. Solitary, rarely more than one nest or pair at a site; very aggressive to intruders. Aerial courtship display by male, which flies over female, extends wings upwards and spreads tail, and extends neck to touch or almost touch female's head. Nest built by both sexes, in one case taking 28 days, an open cup made of mud mixed with grass, lined with hair, grass, rootlets and feathers; affixed to wall or roof up to 5 m below ground in old burrow of aardvark (*Orycteropus afer*), pothole, riverbank, donga, mine or, rarely, culvert or building; nest of other hirundine also occasionally utilized; nests reused, once for 18 years. Clutch 2-4 eggs, normally 3; incubation by female, period 14-17 days, usually 15-16; chicks fed by both sexes, up to 3 times per minute, fledging period 20-26 days; young return to nest for a few nights. Nest losses due mainly to adverse weather, such as rain (causing erosion of site), late frosts, floods, cyclones (leading to entrance becoming obscured by vegetation), and rain or mist reducing efficiency of, or preventing, foraging; in one study, 36% of 22 breeding attempts over 24 years at a territory failed when nest collapsed or parents deserted, 78% of 37 eggs hatched and 93% of chicks fledged; in another study, low hatching success and high chick mortality (only 11% of eggs produced fledglings) were associated with prolonged mist and rain, also 31% of eggs were infertile and inbreeding within small population also suggested as a cause of low success; some indication of higher success on artificial sites, but evictions by *Cecropis cucullata* and *H. albigularis* also recorded at such sites.
Movements. Migratory; post-breeding flocks of 40 or more birds recorded. Absent from breeding grounds mainly end Apr to end Sept; leaves later and returns earlier in N of range. Spends non-breeding period in small area in L Victoria Basin (from NE DRCongo E to extreme W Kenya). Adults often return to same breeding site in successive years, males arriving before females.
Status and Conservation. VULNERABLE. Appendices I & II of CMS (Convention on the Conservation of Migratory Species of Wild Animals). Population estimated at c. 2000 pairs in 1998 and c. 3000 individuals at turn of century; declining owing to destruction of habitat. Locally common in Tanzania and Malawi, but scarce elsewhere; 100 pairs in DRCongo, 400 in Tanzania, 100 in Zambia, 360 in Malawi, 300 in Zimbabwe, 100 in Mozambique, 15 in Swaziland; c. 120 breeding pairs in South Africa, where listed as Critically Endangered. Because of territorial behaviour, breeding density naturally low, 3-4 pairs/km^2; in South Africa nests 300-1000 m (average 400 m) apart. Grassland habitat is being destroyed by afforestation, human settlement, and cultivation or livestock farming, and by the spread of non-native plants, such as pine (*Pinus*) and Australian bracken (*Pteridium*) and wattle (*Acacia*), which eliminate nesting and feeding sites. Overgrazing and frequent fires cause erosion of breeding sites; conversely, too little burning leads to increased obstruction by vegetation, preventing the clear flightpath to the nest required by this species. Another potential threat in South Africa is small-scale mining. Some disturbance of breeding pairs by humans and dogs recorded. Infrequently uses artificial nest-sites, but in E South Africa 81% of 31 sites were in mine workings. Only small numbers breed in protected areas: e.g. in Zimbabwe c. 200 pairs in Nyanga National Park and fewer than 50 pairs in Chimanimani National Park, and in Swaziland about five pairs in Malolotja Nature Reserve. Small populations may also lead to inbreeding problems. Conservation targets are to identify and conserve non-breeding areas; monitor breeding populations; control spread of non-native plants on breeding grounds; and assess effects of fires. Efforts to improve existing breeding sites and to create new ones, mimicking aardvark holes, have been successful.
Bibliography. Allan (1986, 1988), Allan, Gamble *et al.* (1987), Allan, Harrison *et al.* (1997), Anon. 59. Black-and-rufous Swallow
Hirundo nigrorufa

French: Hirondelle roux et noir **German**: Rostbauchschwalbe **Spanish**: Golondrina Rojinegra

Taxonomy. *Hirundo nigrorufa* Bocage, 1877, Caconda, Angola.
Sometimes considered to form a superspecies with *H. atrocaerulea*, but morphological differences probably too great to justify such a treatment. Monotypic.
Distribution. Angola (Cuanza Sul S to N Huíla, E to S Lunda Norte and N Moxico) E to S DRCongo and N Zambia.

Descriptive notes. 13-14 cm; 13-16 g. Distinctive. Has forehead to hindneck and upperparts glossy violet-blue, wings and tail blackish with slight gloss; outer tail feathers slightly elongated; inner webs of rectrices with white edges (rather than patches); entirely rufous below. Differs from *Petrochelidon rufigula* in white edges (not patches) in tail, deeper rufous underparts, lack of rufous on rump. Female is slightly paler than male, with shorter tail. Juvenile is duller, browner above and paler below, tail shorter. VOICE. Song is a shrill warbling; also a strident "eeek".
Habitat. Grassland and savanna, especially seasonally flooded areas and often near water, such as streams; often hunts over miombo woodland. Also observed at edge of a swamp, over a fish pond, and in burnt and cleared woodland.
Food and Feeding. Diet includes flies (Diptera) and beetles (Coleoptera). Feeds alone or in pairs, occasionally in small groups of 4-5 individuals, usually very low, 1-2 m above ground; occasionally higher, especially when not breeding. Often perches on stems, bushes, termite (Isoptera) mounds, or fences. Flies quickly, with rapid wingbeats.
Breeding. Jul-Oct; single-brooded. Solitary, inter-nest distance along one river was 100 m; aggressive towards other hirundines. Aerial courtship display with wings held upwards. Nest-building

takes c. 4 weeks, nest an open cup made of mud and rootlets, lined with grass and sometimes a few feathers, usually affixed 0·2-0·7 m above water, below overhang, on bank of river or stream, once in a pit. Clutch 2-3 eggs, usually 3; incubation and fledging periods not documented.
Movements. Resident or partial migrant. Population in NW Zambia absent from breeding sites in late Nov to early Mar, but non-breeding areas not known; whether post-breeding movements occur elsewhere in range also unknown. Forms flocks of up to 20 after breeding.
Status and Conservation. Not globally threatened. Generally considered uncommon, although locally common. Common in Mwinilunga District, in Zambia; not uncommon in Angola. Potential breeding sites are rather more limited than for some other hirundines, as this species does not use artificial nest-sites.

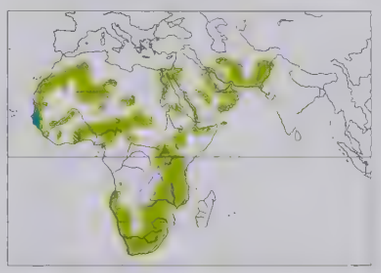
Genus *PTYONOPROGNE* Reichenbach, 1850

60. Eurasian Crag Martin

Ptyonoprogne rupestris

French: Hirondelle de rochers **German**: Felsenschwalbe **Spanish**: Avión Roquero
Other common names: Crag Martin, Mountain/Northern Crag Martin

Taxonomy. *Hirundo rupestris* Scopoli, 1769, Tirol, Austria.
Genus often merged with *Hirundo*, but DNA studies indicate that the two are sister-taxa. Forms a superspecies with *P. fuligula* and *P. concolor*; all three have been considered conspecific, but breeding ranges overlap. Birds from C Asia and S Morocco proposed respectively as races *centralasica* and *theresae* on basis of size, but variation not constant. Monotypic.
Distribution. Breeds S & SC Europe (S from S France, S Germany, Austria, Romania), NW Africa (Morocco E to Tunisia and NE Libya),W Arabian Peninsula, and from Asia Minor, Caucasus and Near East (S to Israel) E to Iran, S Russia (E to SW Siberia) and N Mongolia and, in S, to Himalayas (from Pakistan to Bhutan) and W, N & SC China; winters in Mediterranean region, N & NE Africa (also Senegambia and Guinea-Bissau), Middle East, India and S China.



Descriptive notes. 15 cm; 17-33 g. Has brown-grey crown and upperparts, dark brown wings and tail; tail square, white spots on inner webs of feathers (except inner and outermost pairs, occasionally spots also on outer pair); chin and throat pale with dark speckling, pale buff breast grading into brown-grey belly and brown undertail-coverts; underwing-coverts blackish. Distinguished from very similar *P. fuligula* by generally darker coloration and usually larger size; from *Riparia riparia* by larger size, darker upperparts, underwing and undertail-coverts, white in tail, lack of breastband. Sexes alike. Juvenile has buffy feather edges, throat less dark than adult's and with indistinct mottling. Voice. Soft twittering song; calls include a contact call "prrrt", low- and high-intensity alarm calls "zrrr", "gsigsi", an excitement call "whee", an aggressive "rrr"; a series of notes is uttered during aerial chases of conspecifics.
Habitat. Mountains, crags and coastal cliffs; also around human habitations. In Europe from sea-level to 2500 m, mostly 500-1000 m in alpine valleys on NE/SW slopes; to over 4500 m in Asia. Forages close to cliff faces and over gorges, woodland and villages; outside breeding season also over farmland, meadows, rocky coasts, swamps and lakes.
Food and Feeding. Diet includes flies (Diptera), stoneflies (Plecoptera), caddis flies (Trichoptera), beetles (Coleoptera), bugs (Hemiptera), butterflies and moths (Lepidoptera), hymenopterans (ants and a wasp recorded) and spiders (Araneae); flies and small beetles seem to be main prey. Feeds in pairs or small groups. Flight slow, with frequent steady gliding. Flies back and forth along cliff face in sunny weather; at other times feeds over adjacent land; often flies below level of local dominant land surface, but also ascends high in thermals. Takes insects from rocks, and catches those disturbed as it flies past rock face. Occasionally perches on ground to feed and takes insects from water surface. Forages within 1·5 km of nest; feeding range in Spanish study was c. 0·2-0·25 km² when breeding and c. 1·5 km² in winter; birds roosting on Gibralter thought to feed within 5 km of roost-site.
Breeding. May-Aug; two broods. Solitary, or in small groups of usually 2-20, in Spain average c. 4·5-6·1 pairs (range 1-40); a few larger colonies known, e.g. 60 pairs in Iran, and 25, 50 and 100 pairs in Switzerland, but possibly aggregations of smaller groups; inter-nest distance in groups 10-80 m, average 14·4-16·2 m in one study and 30·5 m in another; will nest with Alpine Swift (*Tachymarptis melba*), *Cecropis daurica*, *Delichon urbicum* and *P. fuligula*. Aggressive to intruders; defends area of c. 200-300 m². Nest built by both sexes, taking 9-20 days, an open half-cup made of mud pellets, lined with grass and feathers, female continues to add lining during incubation; placed in crevice or under overhang on cliff face, also on bridge, or on or in building such as house, hotel, hill fort, castle or church, mainly 6-25 m (range 1-40 m) above ground in one study; nests reused in same and successive seasons. Clutch 2-5 eggs, usually 3 or 4, once 6; incubation from final egg, almost solely by female, 5% by male, at one nest female left 1-6 times per hour, period 13-17 days; hatching synchronous, chicks brooded closely for first few days, mostly by female, then less constantly until c. 10-11 days, fed by both sexes, one feed every 2-5 minutes, nestling period 24-27 days; fledglings fed by parents for further 14-21 days, return to nest to roost.
Movements. Populations in N of range generally migratory; resident in S. Forms post-breeding flocks of up to 400, sometimes associating with other hirundines, and roosts can number 1500-2000 birds (e.g. in caves in Gibralter). European breeders winter mainly in NW Africa but also Senegambia and Guinea-Bissau, Egypt, Red Sea coast and Ethiopia; some overwinter in N Mediterranean, especially on W side. Large passage movements over Strait of Gibralter Oct and Mar. Coastal Mediterranean populations resident, with local post-breeding movements; those breeding inland in Iberian and Balkan Peninsulas move to lower altitudes or the coast. Birds breeding farther E winter in Middle East, India and China; some Asian populations resident but disperse after breeding, e.g. in India and Nepal descends to lower altitudes (mostly below 2000 m) Oct-Mar; in Pakistan moves locally in N, sedentary in S. Vagrant farther N, e.g. in Finland and British Is.
Status and Conservation. Not globally threatened. Widespread and locally fairly common or common, e.g. throughout Mediterranean region. Distribution patchy and breeding irregular in N part of European range; nesting groups at least 1-5 km apart in Switzerland. Breeds only occasionally in Israel and Tunisia. In Europe, main population in Iberian Peninsula; since 1960s, range has been expanding N from Balkans and in Alps and Jura; increased use of bridges and buildings is allowing nesting away from mountain sites, e.g. in villages and towns.

61. Rock Martin

Ptyonoprogne fuligula

French: Hirondelle isabelline **German**: Steinschwalbe **Spanish**: Avión Isabelino
Other common names: Pale Crag Martin (N races); Red-throated Rock Martin (*pusilla*, *bansoensis*, *fusciventris*); African Rock Martin (*anderssoni*, *pretoriae*, *fuligula*)

Taxonomy. *Hirundo fuligula* M. H. K. Lichtenstein, 1842, Baviaan River, Cape Province, South Africa.
Genus often merged with *Hirundo*, but DNA studies indicate that the two are sister-taxa. Forms a superspecies with *P. rupestris* and *P. concolor*; all three have been considered conspecific, but breeding ranges overlap. Taxonomy complex, requires further study. Races appear to form three separate groups: "*obsoleta* group" of pale N races (also comprising *presaharica*, *spatzi*, *buchanani*, *perpallida*, *pallida*, *arabica*), often treated as constituting a separate species; small and dark "*fusciventris* group" (also including *pusilla* and *bansoensis*) of W, C & E Africa; and large-sized "nominate group" (also with *anderssoni* and *pretoriae*) of S Africa. Variation in coloration and size, however, mainly clinal; moreover, all races intergrade with one another, and ranges not clearly demarcated. Proposed race *birwae* (Sierra Leone, Guinea) synonymized with *bansoensis*; birds from N Nigeria and Chad E to Ethiopia and S to DRCongo, Uganda and N Tanzania described as race *rufigula*, but that name invalid, as preoccupied, and therefore synonymized with *fusciventris*. Thirteen subspecies usually recognized.
Subspecies and Distribution.
P. f. presaharica (Vaurie, 1953) - S Morocco, Algeria (except S) and N Mauritania.
P. f. spatzi (Geyr von Schweppenburg, 1916) - S Algeria, SW Libya and N Chad.
P. f. buchanani (Hartert, 1921) - Niger.
P. f. obsoleta (Cabanis, 1850) - Egypt E to N, C & E Arabia and Iran.
P. f. perpallida (Vaurie, 1951) - S Iraq and NE Saudi Arabia.
P. f. pallida Hume, 1872 - E Iran, SW & SE Afghanistan and Pakistan.
P. f. arabica (Reichenow, 1905) - NE Chad (Ennedi), N Sudan, SW Arabia, Eritrea, N Somalia and Socotra.
P. f. pusilla (Zedlitz, 1908) - S Mali E to Ethiopia and Eritrea.
P. f. bansoensis (Bannerman, 1923) - Sierra Leone E to Nigeria and Cameroon.
P. f. fusciventris Vincent, 1933 - S Chad, Central African Republic, W & S Sudan, SW Ethiopia, and E Africa S to Zimbabwe and N Mozambique.
P. f. anderssoni (Sharpe & Wyatt, 1887) - N & SW Angola and N & C Namibia.
P. f. fuligula (M. H. K. Lichtenstein, 1842) - S Namibia, Botswana and W South Africa.
P. f. pretoriae Roberts, 1922 - SW Zimbabwe and S Mozambique S to E South Africa.

Descriptive notes. 13-16 cm; 16-30 g. Nominate race has dark earth-brown crown and upperparts, darker brown wings and tail; tail square, white spots on inner webs of feathers (except central and, usually, outer pairs); chin and throat pinkish-cinnamon, colour extending over upper breast and underwing-coverts; belly and undertail-coverts dark grey-brown. Distinguished from very similar *P. rupestris* by smaller size (usually) and generally slightly paler, greyer coloration; from *Riparia* species by white in tail, no breastband. Sexes alike. Juvenile has buff feather edges. Races differ in size and in depth of colour: *pretoriae* is marginally bigger and paler than nominate; *anderssoni* is paler, greyer and marginally smaller than nominate; *fusciventris* is smaller and darker, dark brown, throat pinkish-fawn, breast tinged rufescent; *bansoensis* is even darker than last, upperparts glossy; *pusilla* is paler than previous races, breast pinkish-grey; *buchanani* differs from last in somewhat paler coloration; *arabica* is paler and greyer, throat light pink, breast light grey-brown with pink wash, slightly larger than last; *spatzi* resembles previous but slightly paler, is more buff below, with less pink tinge; *presaharica* is very like last but slightly paler, more sandy; *obsoleta* is paler and greyer than last, more grey-brown, whitish below; *perpallida* is very pale, whitish-grey above, whitish below; *pallida* is pale sandy grey above, rump paler, buffish-white throat, whitish below. Voice. Not very vocal; song is a soft twittering; calls include a contact call "twee", a "chirp" and a rapid "chir chir chir".
Habitat. Mountains, crags, cliffs, gorges, coasts, also human habitations, including towns and cities; mostly in arid habitats, including deserts. To 3000 m. Also pools, swamps and lakes when not breeding.
Food and Feeding. Diet includes flies (Diptera), beetles (Coleoptera), bugs (Hemiptera), Hymenoptera (including flying ants). Forages in pairs or small groups; mixes with other hirundines and with swifts (Apodidae). Keeps mainly close to cliff and ground; in one study fed within 10 m of ground and 40 m from nest, in another at average of 7 m above ground. Flight slow, with frequent gliding; glides back and forth along cliff face or building. Visits grass fires, and occasionally feeds on ground. Active at dawn and dusk, and feeds late in evening.
Breeding. Feb-Apr in NW Africa, Jan-Jun in Egypt, mainly Mar-May (some to early Jul) in Israel, and Apr-Jun in SW Asia; mainly May-Jun/Jul and Oct-Dec in W Africa, Jan-Mar and Oct-Dec in Ethiopia; in all months in E Africa, peaks varying geographically; Feb in Angola, Feb-Apr and Jul-Nov in Zambia, Jan-Apr and Aug-Nov in Zimbabwe; mainly Aug-Apr (peak Sept-Jan) in S Africa, but in any month after rains in Kalahari Desert; may have up to three broods. Solitary, or sometimes in small, scattered groups of up to 40 pairs: a record of pair nesting in *Cecropis abyssinica*

On following pages: 62. Dusky Crag Martin (*Ptyonoprogne concolor*); 63. Northern House Martin (*Delichon urbicum*); 64. Asian House Martin (*Delichon dasypus*); 65. Nepal House Martin (*Delichon nipalense*); 66. Greater Striped Swallow (*Cecropis cucullata*); 67. Lesser Striped Swallow (*Cecropis abyssinica*); 68. Rufous-chested Swallow (*Cecropis semirufa*); 69. Mosque Swallow (*Cecropis senegalensis*); 70. Red-rumped Swallow (*Cecropis daurica*); 71. Striated Swallow (*Cecropis striolata*); 72. Rufous-bellied Swallow (*Cecropis badia*).

colony. Aggressive to intruders near nest. Nest built by both sexes, sometimes taking several weeks, an open full cup or half-cup made of mud pellets, lined with vegetable fibres and feathers; affixed 3-15 m above ground beneath overhang on rock face, dam or bridge, or to beam or under eaves of building (including tombs, temples) or verandah; nests reused in same and successive seasons, also used for roosting in non-breeding season. Clutch 2-3 eggs in Africa, 3-5 (usually 3) in Middle East and Pakistan; incubation by both sexes, bouts lasting 2-12 minutes, period 13-18 days; chicks fed by both sexes, brood of 3 fed every 1·9 minutes, brooded by both sexes for much of first 3-4 days, fledging up to 25-30 days, but fledglings often flutter between nest and nearby perch for several days; young fed by parents for up to a further 19 days. Nests sometimes usurped by Little and White-rumped Swifts (*Apus affinis* and *A. caffer*). Oldest recorded bird 6 years 9 months.

Movements. Resident in tropics; elsewhere a partial migrant, with local changes in numbers. Forms usually small post-breeding flocks, up to c. 300 individuals; roosts, on buildings, can contain hundreds of birds. Non-breeding visitor to some areas, such as N Senegambia, SW Mauritania and N Somalia; present only during breeding season in some parts of NW Africa. In S Africa, Middle East and Pakistan, resident or moves locally, e.g. to lower altitudes, after breeding. Flocks move around to exploit food concentrations.

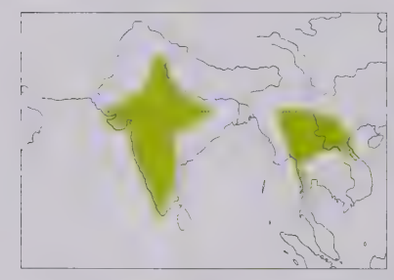
Status and Conservation. Not globally threatened. Widespread and generally common; scarce in Namibia and Botswana. Density at Cape Town, in South Africa, was c. 5 pairs/km^2. Sometimes local because of specialized nest-sites. On other hand, readily nests on buildings, even in cities such as Aswan (Egypt) and Harare (Zimbabwe), and has done so for over a century; has consequently expanded range into less rocky habitat, e.g. since 1970s into Negev Desert (S Israel) and in late 1980s into urban settlements in NE United Arab Emirates; uses farmhouses in the Karoo and Kalahari Deserts. Some nest-site competition from swifts, but no obvious effects on population sizes.

Bibliography. Ali & Ripley (1987), Archer & Godman (1937-1961), Ash & Miskell (1998), Aspinall (1996), Bannerman (1953), Bates (1936), Batten (1943), Benson & Benson (1977), Benson *et al.* (1971), Borrow & Demey (2001), Brooke & Vernon (1961), Bundy & Morgan (1969), Byaruhanga *et al.* (2001), Carr (1984), Cheke & Walsh (1996), Clancey (1964b), Cramp (1988), Dean (2000), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dyson (1976), Earlé (1988a), Elgood *et al.* (1994), Étchécopar & Hüe (1964), Gatter (1997), Ginn *et al.* (1989), Goodman *et al.* (1989), Grimes (1987), Grimmett *et al.* (1998), Hall & Moreau (1970), Harrison *et al.* (1997), Hüe & Étchécopar (1970), Hull (1944), Irwin (1977), Jennings (1980a, 1995), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993a), Meinertzhagen (1930), Moreau (1939a), Moreau & Moreau (1940), Nikolaus (1987), Paz (1987), Penry (1994), Rands *et al.* (1987), Roberts (1992), Schmidt (1964, 1990), Sclater & Moreau (1933), Shirihai (1996), Short *et al.* (1990), Sinclair & Hockey (1996), Skead (1966), Snow & Perrins (1998), van Someren (1958), Stevenson & Fanshawe (2002), Stuart Baker (1934), Tarboton (2001), Tarboton *et al.* (1987), Taylor (1942), Thévenot *et al.* (2003), Tilahun *et al.* (1996), Uhlig & Uhlig (1996, 1998), Ussher (1944), Valverde (1957), Vaurie (1959), Waugh (1978), Zimmerman *et al.* (1996).

62. **Dusky Crag Martin**

Ptyonoprogne concolor

French: Hirondelle concolore **German**: Einfarbschwalbe **Spanish**: Avión Oscuro
Other common names: Dusky Martin



Taxonomy. *Hirundo concolor* Sykes, 1832, Dukhun, India.

Genus often merged with *Hirundo*, but DNA studies indicate that the two are sister-taxa. Forms a superspecies with *P. rupestris* and *P. fuligula*; all three have been considered conspecific, but breeding ranges overlap. Race *sintaungensis* possibly not clearly distinguishable from nominate, which varies in darkness. Two subspecies tentatively recognized.

Subspecies and Distribution.

P. c. concolor (Sykes, 1832) - extreme SE Pakistan and India (from Gujurat, E Rajasthan and Haryana E to W Bihar, S to Kerala and W Tamil Nadu).

P. c. sintaungensis (Stuart Baker, 1933) - E & S Myanmar, S China (S Yunnan), N & E Thailand, N Laos and N Vietnam.

Descriptive notes. 13 cm; 12-14 g. Plumage is mostly dark sooty brown (variable, to blackish), paler below; tail square, white patches except on outermost and innermost pairs; chin, throat and foreneck buffy brown with blackish streaks; underwing-coverts dark brown. Differs from *P. rupestris* and *P. fuligula* in much darker colour, uniformly dark underparts. Sexes alike. Juvenile has rufous-grey feather edges, paler throat. Race *sintaungensis* is darker than nominate, almost black on back, with darker brown underparts. Voice. Twittering song; contact call a soft "chit"chit".

Habitat. Mountainous areas with cliffs and gorges, also lowland areas with suitable breeding sites; also around human habitations, including towns and cities. To 1800 m.

Food and Feeding. Dietary details not known. Feeds alone or in pairs, occasionally in small groups; often associates with other hirundines. Forages around buildings and cliffs; flight slow, with frequent gliding.

Breeding. Jan-Oct; mainly Feb-Mar and after rains in Jul-Aug in India, Feb-May and Jul-Oct in Pakistan; Mar-Apr in SE Asia. Solitary, or small scattered groups if suitable nest-sites abundant. Nest built by both sexes, a half-bowl made of mud pellets, lined with dry grass and feathers, usually placed under overhang up to 30 m above ground on cliff, riverbank, cave wall, bridge, culvert, well, fort, mosque or tomb, or under eaves of other building; old nests repaired and reused. Clutch 2-4 eggs, rarely 5; incubation and brood-feeding by both sexes; incubation and fledging periods not documented.

Movements. Resident, with some local post-breeding movements. Forms small flocks when not breeding. Vagrant in Sri Lanka; possible vagrant in Borneo.

Status and Conservation. Not globally threatened. Generally common to locally common. Common where breeding sites abundant, including in cities such as Bombay (India), but only locally distributed; rare in Pakistan. Fairly common in SE Asia, where possibly more widespread in mountainous areas than is indicated by confirmed breeding records; single breeding record and some sight records from SW Peninsular Malaysia (Selangor), and suspected as occurring more widely in highlands of that region. Has benefited from use of artificial nest-sites.

Bibliography. Ali (1969, 1996), Ali & Ripley (1987), Duckworth *et al.* (1999), Grimmett *et al.* (1998), Jeyarajasingam & Pearson (1999), King *et al.* (1975), Lekagul & Round (1991), MacKinnon & Phillipps (2000), Meyer de Schauensee (1984), Mukherjee (1995), Ripley (1982), Roberts (1992), Robson (2000), Smythies (1986), Stuart Baker (1934), Vaurie (1951b), Vowles & Vowles (1985), Wells (1984), Yu Yixin & Cheng Tsohsin (1962).

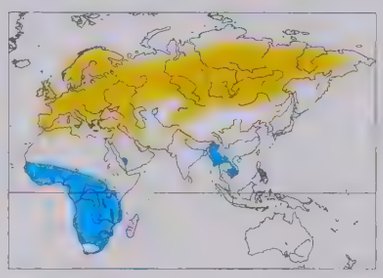
Genus *DELICHON* F. Moore, 1854

63. **Northern House Martin**

Delichon urbicum

French: Hirondelle de fenêtre **German**: Mehlschwalbe **Spanish**: Avión Común
Other common names: House Martin, Common/European/Western House Martin

Taxonomy. *Hirundo urbica* Linnaeus, 1758, Sweden.



Forms a superspecies with *D. dasypus*; sometimes considered conspecific, but breeding ranges overlap (e.g. S of L Baikal). Nominate race exhibits largely clinal decrease in size from N to S, but abrupt size reduction in S Europe; birds in WC Europe sometimes separated as race *fenestrarum*. Race *lagopodum* and nominate breed parapatrically in Buryatia (S & E of L Baikal); review of taxonomic status of former required. Occasionally hybridizes with *Hirundo rustica*. Three subspecies recognized.

Subspecies and Distribution.

D. u. urbicum (Linnaeus, 1758) - W, C & N Europe E to W Siberia; winters mainly sub-Saharan Africa.

D. u. meridionale (Hartert, 1910) - S Europe, N Africa and WC Asia (E to Tien Shan and Kashmir); winters Africa and SW Asia.

D. u. lagopodum (Pallas, 1811) - E Asia from middle and upper R Yenisey, Altai Mts and N Mongolia E to Anadyrland, Sea of Okhotsk and NE China; probably winters mainly SE Asia.

Descriptive notes. 13-14 cm; 16-23 g. Male breeding has glossy blue crown and back, white rump, sometimes white feather bases showing on hindcrown; wings and tail black, tail moderately forked; wholly white below, legs with white feathering. Distinguished from *D. dasypus* by more glossy upperparts, whiter underparts, deeper tail fork. In non-breeding plumage, white on rump, face side, throat and flanks mottled brown-grey. Female has greyer underparts than male. Juvenile is duller, browner (less blue), with tail shorter. Race *meridionale* is smaller than nominate; *lagopodum* has more white on lower back, less deeply forked tail. Voice. Song is a soft twittering; calls include a shrill contact call "prt" or longer "triit-triit, an enticement call "za-za-za" used by males to attract a mate, and a threat call, various warning and alarm calls "trieer", "tsieer" and high-pitched "tsitsitsitsier", and a hissing distress call.

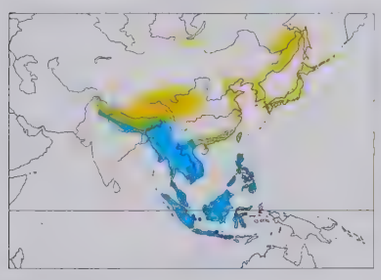
Habitat. Open areas, coastal cliffs, cultivation, and human habitations, including towns and cities; in mountainous areas mostly to 2000 m in Europe, but to 4500 m in Asia. Roosts in nests, sometimes communally, and on trees and cliffs, rarely in reedbeds; also thought to sleep on the wing, especially in winter quarters.

Food and Feeding. Almost entirely insects, predominantly small ones. Diet in S England (mainly nestlings) 60% flies (Diptera), 18% aphids (Homoptera), 11% parasitic Hymenoptera, 5% beetles (Coleoptera), other insects including flying ants; proportion of aphids declines over summer, from 46% in May to 4% in Aug-Sept. Nestling diet in Switzerland 45% dipterans, 33% aphids, 7% other bugs (Hemiptera), 8% mayflies (Ephemeroptera), stoneflies (Plecoptera) and caddis flies (Trichoptera), 3% Hymenoptera, 2% beetles, 1% psocids (Psocoptera); in Poland, 58% hemipterans (mainly aphids), 32% dipterans, 4% coleopterans, 3% hymenopterans; in W Russia (Moscow region), 53% hemipterans, 17% dipterans, 13% ephemeropterans, 8% coleopterans, 6% ants. Other items recorded include small Odonata, small lepidopterans and small orthopterans, and spiders (Araneae). Forages in flocks, sometimes with other aerial feeders. Flight slow, usually high up, average height 21 m in breeding season and over 50 m on wintering grounds. Forages at up to 2 km from nest, average 0·45 km. Occasionally perches on ground, rocks or vegetation to pick up insects; will follow ploughs and large animals to feed on flushed insects.

Breeding. Laying from May in NW & C Europe, end May-Jun in N & NE Europe; starts Mar-May in S Spain and N Africa; Jun-Jul in N Indian Subcontinent (Ladakh, N Kashmir); season ends Aug-Sept or Oct; often two broods. Socially monogamous, but extra-pair paternity occurs (in two studies, 32% and 35% of broods, 15% and 19% of nestlings). In colonies of tens to hundreds of pairs, usually 4-5, colonies larger (mostly 10-50 nests) on cliffs, but colony size often varies annually (from 0 to 513 nests over 25 years in one study); nests often clustered together, abutting each other, entrances at least 8-10 cm apart, small area (radius of c. 10 cm) around entrance defended. Male attracts female by calling and following her, approaches and sings when she perches, potential partners often initially mutually aggressive; copulation mostly inside nest, soliciting male, if accepted, seizes female's crown or nape and mounts; male guards mate during nest-building and egg-laying. Nest built by both sexes, taking 8-18 days (average 10·4 days), enclosed, with small entrance hole near top, made of mud pellets, lined with vegetable fibres and feathers; attached to outside of building or, less often, bridge, usually under overhang, sometimes inside building (increasingly so in some areas, e.g. Belgium and N France), occasionally on natural sea cliff or rock face, rarely in cave or tree; nests reused in same and successive seasons; old nest of *Hirundo rustica* occasionally used. Clutch 1-7 eggs, normally 4-5, e.g. of 882 clutches in Germany 38% were of 4 eggs, 29% of 5, 23% of 3, 5% of 6, 4% of 2 and 1% of 7; clutch size decreases over season, e.g. means of 4·8 for first clutch and 3·3 for second; incubation by both sexes, male contribution variable, equal to female's in Norwegian study, less in Finnish one, in Finland bouts by female averaged 13 minutes, by male 9 minutes, incubation period 14-16 days; hatching often asynchronous; chicks brooded by both sexes, male contribution variable, brooding intense for first few days, declines over days 4-11, also fed by both sexes, usually in bouts, with periods of c. 30 minutes with few feeds; fledging 22-32 days, depending on brood size and weather; fledglings return to nest to roost for several days, fed by parents for a few days, sometimes stay in colony for several weeks. Breeding success 56-81%; nestling mortality from starvation can be high in bad weather. Oldest recorded bird 14 years 6 months.

Movements. Migratory. Forms flocks of several hundreds or thousands after breeding. Main migration periods Sept-Oct and Apr-May. W populations migrate N-S across Europe, winter mainly in sub-Saharan Africa; records in Africa scarce and widely scattered, largest numbers in S; not recorded in roosts. From ringing studies, Baltic and Scandinavian breeding populations appear to winter in Zambia, Zimbabwe and South Africa, and W European ones in W Africa; S European populations may winter in Sahel zone. Common and widespread on passage through India, where a few individuals may winter in S. E populations probably winter in S & SE Asia. Generally returns to same breeding site in successive years, males more so than females; older individuals arrive before first-years. Vagrants recorded in several countries, e.g. Greenland, Iceland, USA (Alaska), Bermuda.

Status and Conservation. Not globally threatened. Common and widespread, but numbers fluctuate locally. In Europe, population stable overall but some recent declines, e.g. in region from Scandinavia to Netherlands and Germany; in Brussels (Belgium) declined by 75% in 1982-1992, and Netherlands population in 1990s was only 35% of that in 1965. Has occasionally bred outside normal range, as in Iceland, Faeroes and Malta. Population in Israel increased from a few pairs in 1940s to c. 2000 pairs from 1970s. Adverse weather can have marked effect during breeding and migration. Suffers nest-site competition from House Sparrows (*Passer domesticus*); in study in Poland, avoidance of this species thought to be reason for recent change in breeding sites from outside walls to inside buildings. In Europe, nests in towns and cities more readily than does *Hirundo rustica*. Has benefited from building developments, which provide additional nesting sites, and from reduction of pollution in cities such as London (UK), which leads to increase in food supply; in Berlin (Germany), 36% increase between 1979 and 1983/84. Readily utilizes specially designed nestboxes.



Bibliography. Adamian & Klem (1999), Ali & Ripley (1987), Andrew (1993), Antón (1984), Archipenko *et al.* (1968), Ash (1992a), Balat (1974), Bell (1983), Beser (1968), Bouldin (1968), Bruderer (1975), Bryant (1973, 1975, 1978a, 1978b, 1979, 1988, 1989), Bryant & Gardiner (1979), Bryant & Turner (1982), Bryant & Westerterp (1980, 1982, 1983a, 1983b), Bulgarini & Visentin (1997), Buschendorf (1975), Chapin (1953), Christie, de Lope *et al.* (2001), Christie, Møller & de Lope (1998), Christie, Møller, Saino & de Lope (2000), Clancey (1950), Clark & McNeil (1980), Cramp (1988), Cramp & Gooders (1967), Cretin *et al.* (1971), Creutz (1961), Daoudi *et al.* (2002), Darolova (1997), Dementiev *et al.* (1968), Dolnik & Kinzhewskaja (1980), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Étchécopar & Hüe (1964), Fletcher (1987), Fouarge (1992), Germogenov (1985), Glutz von Blotzheim & Bauer (1985), Goodman *et al.* (1989), Guan Guosheng *et al.* (1988), von Gunten (1961, 1963), von Gunten & Schwarzenbach (1962), Gustafson *et al.* (1985), Hagemeijer & Blair (1997), Hails & Bryant (1979), Harrison *et al.* (1997), Heath *et al.* (2000), Hill (1992, 1997, 2000), Hund (1976), Hund & Prinzinger (1979a, 1979b, 1985), Jonkers & Leys (1994), Kaminski, Choinski & Wotosiuk (1993), Kaminski, Wotosiuk & Choinski (1993), Keith *et al.* (1992), Kondélka (1978), Kozená (1975), Lifjeld & Marstein (1994), Lind (1960, 1962, 1963, 1964), Löhrl (1971), de Lope (1986, 2003c), de Lope & da Silva (1988), de Lope, González *et al.* (1993), de Lope, Møller & Cruz (1998), Loske (1986b), Lyulceva (1974), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993a), McNeil & Clark (1987), Menzel (1984), Milwright (1990), Møller (1984), Møller *et al.* (1994), Moreno & Møller (1996), Newman *et al.* (1985), Oliver (1975), Pajuelo *et al.* (1992), Palmgren (1960), Pons (1989), Prinzinger & Siedle (1986, 1988a, 1988b), Prinzinger *et al.* (1979), Rheinwald (1970, 1971, 1973, 1975a, 1975b, 1977, 1979), Rheinwald & Gutscher (1969a, 1969b), Rheinwald & Schulze-Hagen (1972), Rheinwald *et al.* (1976), Riley *et al.* (1995), Roberts (1992), Rydzewski (1978), Sharrock (1976), Shirihai (1996), Snow & Perrins (1998), Steen *et al.* (1989), Stoepel (1984), Stremke & Stremke (1985), Tebb & Ranner (2002), Telleria *et al.* (1999), Tryjanowski & Kuczynski (1999), Turner (1982a), Uribe & Hostau (1988), Vaurie (1951b), Westerterp & Bryant (1984), Whittingham & Lifjeld (1995a, 1995b).

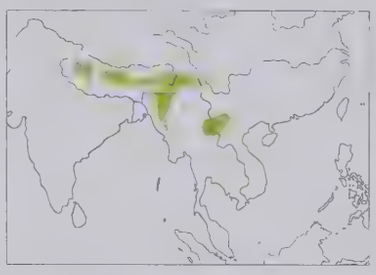
64. Asian House Martin

Delichon dasypus

French: Hirondelle de Bonaparte **German**: Kaschmirschwalbe **Spanish**: Avión Asiático
Other common names: Asian Martin; Kashmir House Martin (*cashmeriense*)

Taxonomy. *Chelidon dasypus* Bonaparte, 1850, Borneo.
Forms a superspecies with *D. urbicum*; sometimes considered conspecific, but breeding ranges overlap, e.g. S of L Baikal. Three subspecies recognized.
Subspecies and Distribution.
D. d. cashmeriense (Gould, 1858) - Himalayas from Pakistan E to SC China; winters N India and SE Asia.
D. d. dasypus (Bonaparte, 1850) - SC & SE Russia (Khamar-Daban, Ussuriland, Sakhalin) and Kuril Is S to NE China, Korea and Japan; winters SE Asia S to Greater Sundas and Philippines.
D. d. nigrimentale (Hartert, 1910) - S & E China and Taiwan; winters SE Asia.

Descriptive notes. 13 cm; 18 g. Has glossy blue crown and back, white rump and shorter uppertail-coverts; wings and tail blackish-brown, tail slightly forked; underparts white with grey wash, legs with white feathering; underwing-coverts grey-brown. Differs from *D. urbicum* in less glossy plumage, darker underparts, less deeply forked tail. Sexes alike. Juvenile is duller, dusky wash on underparts, tertials tipped white, tail squarer. Races differ mainly in size: *cashmeriense* is smaller than nominate, also has brighter blue upperparts, purer white rump and underparts; *nigrimentale* is smallest. Voice. Song is a soft twittering; shrill contact call.
Habitat. Valleys and gorges in mountainous areas and sea coasts, also human habitations. Mostly above 1500 m, and to over 3000 m; breeds at 1300-4800 m in India, often over 3000 m in Pakistan, and to 4000 m in Nepal.
Food and Feeding. Diet includes small dipteran flies (especially Nematocera and Brachycera, also Syrphidae), bugs (Hemiptera) including homopterans, beetles (Coleoptera), Hymenoptera (including winged ants), small Lepidoptera, caddis flies (Trichoptera), lacewings (Neuroptera), stoneflies (Plecoptera), springtails (Collembola). Feeds in flocks, high up, with slow flap-and-glide flight. Presence in diet of springtails and caterpillars suggests occasional feeding while perched.
Breeding. Mar-Oct in N, Apr-Jul in S; may have up to three broods, possibly only one in Himalayas. Colonial, in small groups; nests often scattered at a site, but sometimes close together. Nest built by both sexes, made of mud pellets, often mixed with grass, and lined with feathers and occasionally other material, such as pine (*Pinus*) needles and moss, shape variable, depending on where built, can be either enclosed with an entrance hole or open at top; attached to cliff face, cave wall, or occasionally on bridge or building, such as house, temple, hotel or power plant, usually under overhang. Clutch 2-6 eggs, usually 3 or 4; incubation and brood-feeding shared by both sexes, incubation and fledging periods not documented; fledglings return to nest for a few nights to roost. Oldest recorded bird 6 years 4 months.
Movements. Largely migratory; extent of winter ranges unclear. NE populations (nominate race) migrate S to, primarily, Malay Peninsula; uncommon in Singapore, and rare in Philippines, Borneo, Sumatra and Java; some winter in S Japan. W race (*cashmeriense*) moves to lower altitudes, occurring in non-breeding season from N India E to SE Asia. Race *nigrimentale* perhaps mainly resident.
Status and Conservation. Not globally threatened. Locally common. Extent of range in S Russia uncertain: recent expansion into Khamar-Daban region; any breeding localities between this region and Ussuriland and Sakhalin not yet known. Restricted to natural nest-sites to greater degree than is *D. urbicum*.



Bibliography. Ali & Ripley (1987), Austin & Kuroda (1953), Bates & Lowther (1952), Brazil (1991), Carey *et al.* (2001), Cheng Tsohsin (1987), Dementiev *et al.* (1968), Dickinson *et al.* (1991), Duckworth *et al.* (1999), Dyrnev *et al.* (1983), Étchécopar & Hüe (1983b), Evans (1994), Glutz von Blotzheim & Bauer (1985), Gore & Won Pyongoh (1971), Grimmett *et al.* (1998), Hasson (1976), Inskipp & Inskipp (1991), Jahn (1942), Jeyarajasingam & Pearson (1999), Kennedy *et al.* (2000), Knystautas (1993), MacKinnon & Phillipps (1993, 2000), van Marle & Voous (1988), Medway & Wells (1976), Roberts (1992), Robson (2000), Smythies (1999), Stepanyan (1990), Stepanyan & Vasilchenko (1980), Stuart Baker (1934), Vasilchenko (1987), Vaurie (1954b), White & Bruce (1986).

65. Nepal House Martin

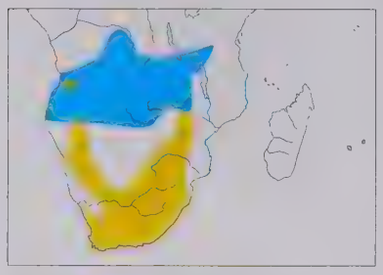
Delichon nipalense

French: Hirondelle du Népal **German**: Nepalschwalbe **Spanish**: Avión Nepalí
Other common names: Nepal Martin

Taxonomy. *Delichon nipalensis* F. Moore, 1854, Nepal.
Plumage variation somewhat clinal, amount of black on throat increasing from W to E. Two subspecies recognized.
Subspecies and Distribution.
D. n. nipalense F. Moore, 1854 - Himalayas from Nepal and SE Tibet E to W Myanmar.
D. n. cuttingi Mayr, 1941 - NE Myanmar, S China (extreme SW Yunnan), NE Thailand, N Laos and NW Vietnam (W Tonkin).

Descriptive notes. 12 cm; 14-16 g. Male has glossy blue crown and back, blue on side of head extending well below eye; rump white, uppertail-coverts white with dark bands; wings and tail brownish-black, tail square-ended; chin and upper throat black, lower throat to abdomen white, undertail-coverts black, legs with white feathering; underwing-coverts dark grey-brown. Distinguished from *D. urbicum* and *D. dasypus* by more extensive blue-black on side of head, black upper throat, black undertail-coverts, square tail. Female is greyer below than male. Juvenile is duller, with less black on throat, buffy underparts. Race *cuttingi* is larger than nominate, with more black on throat. Voice. Not very vocal; high-pitched "chi-i" recorded in flight.
Habitat. Valleys and mountain ridges, open areas with cliffs; also around villages. Breeds to at least 3500 m in Nepal, at 1000-4000 m in India, and to c. 1850 m in SE Asia; lower in non-breeding season, down to 300 m, locally 150 m.
Food and Feeding. Diet includes flies (Diptera). Feeds in flocks, sometimes with other hirundines and swifts (Apodidae), and often high up; flight a mix of gliding and swooping. Often forages along cliffs and over treetops.
Breeding. Generally Mar/Apr-Sept, varying locally; may be double-brooded. Colonial, in groups of tens or hundreds of pairs, often 25-50, some of c. 700 pairs recorded; nests usually not contiguous. Nest built by both sexes, enclosed and with small entrance hole, made of mud pellets, lined with grass and feathers; attached to cliff face, usually under overhang, rarely on artificial site but once a group of three nests on wooden beam in house; nest often used for roosting throughout year. Clutch 3-4 eggs, occasionally 5; incubation and brood-feeding by both sexes, incubation and fledging periods not known.
Movements. Resident; sometimes moves short distances, especially to lower altitudes, after end of breeding.
Status and Conservation. Not globally threatened. Nominate race common to fairly common; widespread and fairly common in Nepal, locally fairly common in India, common in Bhutan. In E of range (*cuttingi*) generally uncommon, and scarce in S China (extreme SW Yunnan). More or less restricted to areas with suitable natural nest-sites, as appears reluctant to exploit artificial ones.

Bibliography. Ali & Ripley (1987), Cheng Tsohsin (2002), Delacour & Jabouille (1940), Duckworth *et al.* (1999), Étchécopar & Hüe (1983b), Grimmett *et al.* (1998), Inskipp, C. & Inskipp (1991), Inskipp, C. *et al.* (1999), Inskipp, T. *et al.* (1996), King (1997), Lister (1954), MacKinnon & Phillipps (2000), Meyer de Schauensee (1984), Ripley (1982), Robson (2000), Smythies (1986), Stanford & Mayr (1941), Stresemann & Stresemann (1969), Stuart Baker (1934), Tye & Tye (1986), Vaurie (1951b, 1959).



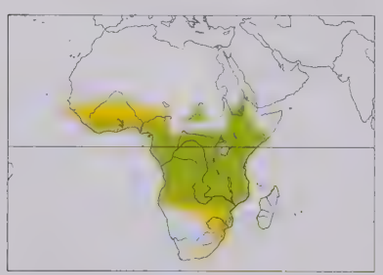
Genus *CECROPIS* Boie, 1826

66. Greater Striped Swallow

Cecropis cucullata

French: Hirondelle à tête rousse **German**: Kapschwalbe **Spanish**: Golondrina Cabecirrufa
Other common names: Streaked Swallow, Larger Stripe-breasted Swallow

Taxonomy. *Hirundo cucullata* Boddaert, 1783, Cape of Good Hope, South Africa.
Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Often considered to form a superspecies with *C. abyssinica*, although ranges overlap widely in S Africa. Monotypic.
Distribution. Breeds Angola, and from C Namibia, SE Botswana and E & C Zimbabwe S to South Africa; migrates N to N Angola, Zambia, S DRCongo and SW Tanzania.
Descriptive notes. 18-20 cm; 19-35 g. Has forehead and crown dark rufous-chestnut, neck side and hindneck paler, back glossy deep blue, rump and shorter uppertail-coverts light rufous-chestnut; wings and tail brownish-black, elongated outer tail feathers forming long streamers, white patches on inner webs of rectrices (except innermost two pairs); underparts buff with narrow sepia streaks (visible only at close range), undertail-coverts white with buffy tinge; underwing-coverts buffy white. Distinguished from *C. abyssinica* by larger size, darker crown, much finer streaking below. Female has shorter tail than male. Juvenile is duller, crown blacker, rump paler, inner secondaries and wing-coverts with tawny tips, tail shorter. Voice. Song starts with few "chrrp" notes and ends in descending trill; also a "chrrp" and a plaintive "wheep".



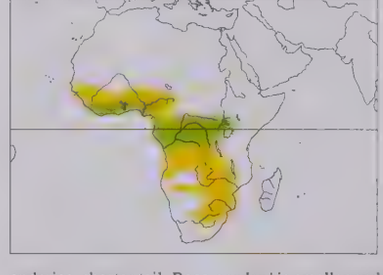
Habitat. Semi-arid karoo, open grassland, including montane grassland above 2000 m; often near water; also cultivation, and human habitations. Avoids wooded areas. Generally at higher elevations than *C. abyssinica*.
Food and Feeding. Diet includes flying ants (Hymenoptera); mulberries (*Morus*) and *Acacia cyclops* seeds occasionally taken, and latter recorded as sometimes fed to nestlings, especially in inclement weather. Feeds alone or in pairs; mixes with other swallows and swifts (Apodidae). Forages usually close to nest-site, and low over ground; flight slow, slower than that of *C. abyssinica*. Also hovers near or clings to acacia pods to extract the seeds. Visits grass fires.
Breeding. Mainly Nov-Mar in Namibia, Nov-Apr in Botswana, Aug-Mar in Zimbabwe and Sept-May (peak Oct-Dec) in South Africa; may have up to three broods, and four recorded in one nest. Solitary, but more than one nest can be present on single building. Male aerial display with shallow wingbeats and song, leads her to nest; throws back head and puffs out throat feathers when singing. Nest built by both sexes, taking 2-3 weeks, enclosed, with tubular entrance, made of mud pellets, lined with grass and feathers; usually affixed high up to underside of horizontal surface of rock face, cave, tree, bridge, culvert, mine, or barn or other building; other nest sometimes used as a base, also nestbox or crevice adapted by addition of entrance tunnel; nests reused in same and successive seasons. Clutch 2-4 eggs, usually 3; incubation by female, period 16-20 days, mostly 18 days; hatching asynchronous, chicks fed by both sexes, fledging period 23-30 days; young return to nest for further 9-22 days. Nest losses due to bad weather, infestation by parasites, i.e. hippoboscid flies (*Ornithomya*), nest falls from corrugated roofs, also nest usurpation by other species, such as White-rumped Swift (*Apus caffer*), which will throw out nestlings, *C. semirufa*, and chats (of genera *Myrmecocichla* and *Thamnolaea*). Oldest recorded bird 6 years 5 months.
Movements. Migratory. Forms small post-breeding flocks of up to 30 individuals. Migrates N in Mar-Apr, spending non-breeding season in Angola, S DRCongo, SW Tanzania and Zambia; recorded also in S PRCongo. May migrate mainly through Namibia and Botswana; may also occur on passage in Zimbabwe; recorded largely on passage in Zambia Apr-May and Sept-Nov. Returns mid-Jul to E South Africa, Aug to Cape and Namibia, and Sept-Oct to Swaziland, KwaZulu-Natal and Botswana. Will return to same nest in successive years, males more so than females.
Status and Conservation. Not globally threatened. Mostly common; scarcer in N & W of range. Readily uses wide variety of artificial nest-sites, which may have allowed its numbers to increase.
Bibliography. Aspinwall (1972), Benson & Benson (1977), Benson *et al.* (1971), Borrow & Demey (2001), Britton (1980), Broekhuysen (1960), Clancey (1964b), Dean (2000), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Earlé (1987d, 1987h), Every (1988), Ginn *et al.* (1989), Grobler & Grobler (1988), Harrison *et al.* (1997), Hockey *et al.* (1989), Keith *et al.* (1992), Lippens & Wille (1976), Mackworth-Praed & Grant (1963, 1973), Maclean (1993a), Martin & Pepler (1997a), Oates (1991), Oatley (2002a), Pedersen (2000), Penry (1994), Pepler & Martin (1997), Pringle (1948, 1989), Roos & Roos (1989), Schmidt (1962, 1990), Shillingford (1965), Short *et al.* (1990), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Stevenson & Fanshawe (2002), Tarboton (2001), Waugh (1978), Woollard & Woollard (1989).

67. **Lesser Striped Swallow**

Cecropis abyssinica

French: Hirondelle striée **German**: Maidschwalbe **Spanish**: Golondrina Abisinia
Other common names: Striped Swallow

Taxonomy. *Hirundo abyssinica* Guérin-Méneville, 1843, Ethiopia.
Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Often considered to form a superspecies with *C. cucullata*, although ranges overlap widely in S Africa. Race *unitatis* intergrades with nominate in S Sudan and Kenya, and probably overlaps in range with *ampliformis* in S. Six subspecies recognized.
Subspecies and Distribution.
C. a. puella (Temminck & Schlegel, 1845) - Senegambia and Sierra Leone E to N Cameroon.
C. a. maxima (Bannerman, 1923) - SE Nigeria, S Cameroon and SW Central African Republic; also Bioko (Fernando Póo).
C. a. bannermani (C. H. B. Grant & Mackworth-Praed, 1942) - W & SW Sudan and NE Central African Republic.
C. a. abyssinica (Guérin-Méneville, 1843) - E Sudan and Ethiopia.
C. a. unitatis (W. L. Sclater & Mackworth-Praed, 1918) - Equatorial Guinea and Gabon E to S Sudan, Kenya and S Somalia, S to C Angola, E Zambia, Zimbabwe, E Botswana, Mozambique and E South Africa.
C. a. ampliformis (Clancey, 1969) - S Angola and N Namibia E to W Zambia and NW Zimbabwe.



Descriptive notes. 15-19 cm; 16-27 g. Nominate race has forehead to nape, ear-coverts and neck rufous-chestnut, back glossy deep blue, rump and shorter uppertail-coverts rufous-chestnut; wings and tail blackish-brown, elongated outer tail feathers forming long streamers, white patches on inner webs of rectrices (except innermost two pairs), largest on outer two pairs; underparts white with broad sepia streaks, streaks heaviest on throat and upper breast; undertail-coverts white with buffy tinge; underwing-coverts buffy. Distinguished from *C. cucullata* by smaller size, paler rufous crown, bolder streaks below. Female has shorter tail than male. Juvenile is duller, crown darker, rump paler, tawny tips of wing-coverts and inner secondaries, shorter tail. Race *puella* is smaller than nominate, finer streaks on underparts; *maxima* is large, with bold streaks, more chestnut crown; *bannermani* has pale crown, streaks very fine; *unitatis* is large, with bold streaks; *ampliformis* resembles last, but with heavier, blacker streaks. VOICE. Vigorous song, with initial squeaky notes followed by descending nasal ones; also a wheezy "cheeew".
Habitat. Grassland, savanna, open woodland, forest edge and clearings, cultivation and human habitations; less often in mangroves, and river valleys in forested areas. Large roosts (200-300 individuals) recorded in sugar-cane fields. Mostly to c. 2000 m. Occurs in more wooded habitat and at generally lower altitudes than *C. cucullata*.
Food and Feeding. Diet includes Hymenoptera (such as flying ants and bees), beetles (Coleoptera) and flies (Diptera), also lepidopterans; also eats fruit from pigeon wood tree (*Trema orientalis*) and seeds of *Acacia cyclops*. Feeds alone, in pairs, or in flocks of up to 100 individuals, mostly in smaller groups of 5-20; mixes with other hirundines and swifts (Apodidae). Forages at average of 6 m above ground, also often 10-20 m over treetops, and often over water. Flight includes much gliding but can be fast and direct; more manoeuvrable than *C. cucullata*. Also hovers over vegetation to take caterpillars, and feeds around other animals on flushed insects; perches when eating fruit.
Breeding. Mainly in wet season; N of equator mainly Mar-Jul/Aug (e.g. Mar and Jul in Senegambia, from Apr in Liberia, Mar-May in Sierra Leone, Mar-Jul in Togo and Nigeria, Mar-Aug in Ghana and Ethiopia, Jul-Aug in Sudan), but probably all year in Gabon; mostly Feb-Aug and Oct-Dec in E Africa; Jan-Feb and Jun-Nov in Angola, Jul-Oct in DRCongo, May-Aug in W Zambia and Sept-Apr in E, Jul-Feb in Malawi, Mar-Oct in Namibia and N Botswana, most months but mainly Sept-Jan in Zimbabwe (races *unitatis* and *ampliformis* probably overlap in range, but former breeds Aug-May, with peak Aug-Dec, and latter breeds Mar-Oct); May-Aug and Oct-Dec in Mozambique, and Aug-May (peak Nov-Dec) in South Africa; may be double-brooded. Solitary, or in small groups of usually fewer than 10 pairs (one of 50), but up to 70 pairs on bridges; nests in groups usually well spaced, at least 25 cm apart in one. Nest built by both sexes, taking up to 7 weeks, an enclosed bowl with entrance tunnel, made of mud pellets, lined with grass and feathers; usually a couple of metres or more above ground, affixed to underside of horizontal surface of cave, rock, riverbank, cliff, tree, building (either inside or under eaves) or verandah, culvert, mine shaft, well or bridge; old hirundine nest sometimes used as base, then enclosed and tunnel added, in one case a pair of *Hirundo smithii* evicted first; will also add tunnel to nestbox; nests reused, sometimes by different individuals. Clutch 2-4 eggs, usually 3; incubation by female, 14-21 days; chicks fed by both sexes, 3-9 feeds per hour, fledging period 17-28 days; young return to nest for several days to roost. Nests sometimes usurped by White-rumped Swift (*Apus caffer*) and Mocking Cliff-chat (*Thamnolaea cinnamomeiventris*). Oldest recorded bird 5 years 11 months.
Movements. Mainly resident, with some local post-breeding movements, near equator; mainly a wet-season breeding visitor in N & S of range. Forms post-breeding flocks and roosts of up to a few hundred birds. S population migrates N to lower latitudes; a few overwinter in breeding range, e.g. along KwaZulu-Natal coast and the lowveld of E South Africa and Swaziland. In Zimbabwe, migrants appear after breeding population has left. Vagrant in Oman.
Status and Conservation. Not globally threatened. Generally common and widespread; one of the most abundant hirundines in Africa, but sometimes only locally common. Avoids heavily forested areas, and is uncommon in some parts, e.g. Senegambia, Sudan, Botswana, Namibia. Recorded in Liberia only since 1962, now breeding in large groups on bridges; possibly overlooked before. Deforestation and extensive use of artificial nest-sites have probably allowed numbers to increase, but new sites in open country may lead to competition with *C. cucullata* and, possibly, *C. semirufa*.

68. **Rufous-chested Swallow**

Cecropis semirufa

French: Hirondelle à ventre roux **German**: Rotbrustschwalbe **Spanish**: Golondrina Pechirrufa
Other common names: Red-breasted Swallow

Taxonomy. *Hirundo semirufa* Sundevall, 1850, Magliesburg, Transvaal, South Africa.
Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Forms a species group with *C. senegalensis*. Individuals in S part of range of *gordoni* proposed as separate race *neumanni*; further study needed. Nominate varies clinally in tail length in SW, longest in S. Two subspecies recognized.
Subspecies and Distribution.
C. s. gordoni (Jardine, 1851) - Senegambia and Sierra Leone E to CW & S Sudan, Uganda, SW Kenya, extreme NW & N Tanzania and Rwanda, S to N Angola and C DRCongo.
C. s. semirufa (Sundevall, 1850) - SW, C & E Angola, and from S DRCongo, Zambia and W Malawi S to N Namibia, N & E Botswana, NE South Africa and Swaziland.

Descriptive notes. 24 cm; 25-40 g. Has glossy blue-black crown and upperparts, rufous neck side, rump and underparts; wings and tail blue-black, elongated outer tail feathers forming long streamers, white patches on inner webs of rectrices (except central two pairs), largest on outer feathers; underwing-coverts pale rufous. Distinguished from *C. senegalensis* by smaller size, longer tail-streamers, no white on throat, dark of crown extending below eye, white in tail; from *C. daurica* by white spots in tail, lack of rufous collar. Female has shorter tail than male. Juvenile is duller, with paler underparts, buff tips of wing-coverts and secondaries, shorter tail. Race *gordoni* is smaller and less rich rufous than nominate. VOICE. Song is a soft gurgling; also a plaintive "seeur", a short "chip" and an alarm call "weet-weet".
Habitat. Open country, mostly to 1500 m. Grassland, savanna, scrub, woodland clearings, farmland, human habitations, often near water. Found in less wooded areas than those favoured by *C. senegalensis*.
Food and Feeding. Diet includes hymenopterans (flying ants), flies (Diptera), beetles (Coleoptera). Forages in pairs or small groups; large numbers will visit grass fires. Feeds with other swallows, often low over ground; flight slow and buoyant, with frequent gliding. Occasionally hovers over vegetation.
Breeding. In rains in W Africa, e.g. Apr-Aug in Liberia, Apr-Sept in Nigeria, Mar-Jul in Cameroon; Apr-Jul and Oct-Dec in DRCongo, Jul-Aug in Sudan, May-Jun in Uganda, Apr-Jun in Kenya, Oct-

Jan/Feb in Zambia and Malawi, Sept and Feb in Botswana; Aug-Apr in Zimbabwe (peak Oct-Jan) and South Africa (peak Nov-Jan); double-brooded. Monogamous, but bigamous male recorded. Solitary. Nest built by both sexes, in two cases taking 13 and 16 days, retort-shaped with long tunnel entrance, made of mud, lined with grass, wool and feathers; usually within 1 m of ground and in wide variety of natural and artificial sites, including overhanging bank, rock face, culvert, bridge, rafter in house, shed roof, chapel, window, drainpipe, electricity tower, hollow tree, fallen log, termite (Isoptera) mound, aardvark (*Orycteropus afer*) hole, warthog (*Phacochoerus africanus*) hole; nests reused in successive years. Clutch 1-6 eggs, normally 3; incubation by female, sitting for as little as 14% of daylight hours, period 16 days; fledging period 23-25 days; young continue to sleep in nest for up to 15 days. In one study, 80% of 175 eggs hatched, 74% of 140 chicks fledged; 82% of first clutches and 44% of second clutches successful; losses due to desertion, eggs falling from nest, chick starvation; nests sometimes usurped by White-rumped Swift (*Apus caffer*). Oldest recorded bird 5 years 9 months.

Movements. Resident near equator; breeding visitor in N & S of range, migrating mainly to tropical areas. Present mainly Apr-Dec (most frequent Jun-Nov) in Gambia, May-Sept in N Ghana, N Nigeria and Cameroon, Apr-Oct in Sudan; numbers in Liberia lower in Nov-Dec than in other months, highest Jan-Apr. S of equator, occurs mainly Nov-May in Tanzania and Aug/Sept-Mar/Apr in S Africa.

Status and Conservation. Not globally threatened. Varies from uncommon to locally common. Recent expansion to S & E, especially in South Africa, perhaps linked to road construction, with bridges and culverts, housing developments and woodland clearance increasing the availability of breeding habitat. Artificial nest-sites exploited extensively, and in some areas used far more than are natural sites, and species thus benefits from human activities.

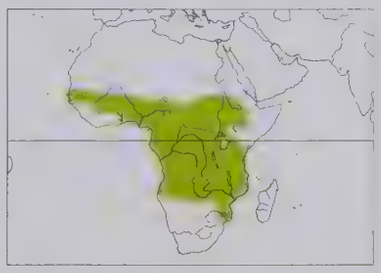
Bibliography. Aspinwall (1980d), Bannerman (1939, 1953), Barlow *et al.* (1997), Benson & Benson (1977), Benson *et al.* (1971), Bijnens & Upoki (1992), Borrow & Demey (2001), Brosset & Érard (1986), Brown & Britton (1980), Byaruhanga *et al.* (2001), Cheke & Walsh (1996), Christy & Clarke (1994), Clancey (1964b, 1982, 1990c), Cooper (1963), Dean (2000), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Earlé (1987d, 1987f, 1989), Earlé & Brooke (1989), Elgood *et al.* (1994), Fishpool & Evans (2001), Gartshore *et al.* (1995), Gatter (1997), Ginn *et al.* (1989), Gore (1990), Grimes (1987), Harrison *et al.* (1997), Irwin (1981), Keith *et al.* (1992), Lewis (1982), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981), Macdonald (1984), Mack (1972), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993a), Nikolaus (1987), Penry (1994), Plowes (1944), Priest (1935), Roberts (1939), Serle (1950a, 1950b), Short *et al.* (1990), Sinclair & Hockey (1996), Stevenson & Fanshawe (2002), Tarboton (2001), Tree (1987), Vincent (1949), Young (1946), Zimmerman *et al.* (1996).

69. **Mosque Swallow**

Cecropis senegalensis

French: Hirondelle des mosquées **German**: Senegalschwalbe **Spanish**: Golondrina Senegalesa
Other common names: African Mosque Swallow

Taxonomy. *Hirundo senegalensis* Linnaeus, 1766, Senegal.



Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Forms a species group with *C. semirufa*. Race *saturatior* intergrades with nominate in Sudan and with *monteiri* in SE Kenya (area between Nairobi and Mombasa). Three subspecies recognized.

Subspecies and Distribution.

C. s. senegalensis (Linnaeus, 1766) - extreme S Mauritania and Senegambia E to N Ghana, N Nigeria, N Cameroon, S Chad and SW Sudan.

C. s. saturatior (Bannerman, 1923) - S Ghana E to S Cameroon, S Sudan and Ethiopia and S to PR Congo, N DRCongo, Burundi and N & S Kenya.

C. s. monteiri (Hartlaub, 1862) - Angola and S DRCongo E to S Kenya, S to N Namibia, N Botswana, Zimbabwe, Mozambique and extreme NE South Africa.

Descriptive notes. 24 cm; 38-54 g. Nominate race has glossy purple-blue or steel-blue crown and back, rufous collar which becomes very narrow on hindneck and is sometimes broken by dark blue feather tips, dark rufous rump; wings black with blue gloss, tail glossy blue-black, elongated outer tail feathers forming long streamers; cheeks, chin and throat cream to pale rufous; underparts rufous, paler on breast, and darker on flanks, abdomen and undertail-coverts; underwing-coverts creamy white to pale fawn. Distinguished from *C. semirufa* by larger size, shorter tail-streamers, whiter underwing-coverts, no white tail patches; from *C. daurica* by larger size, paler throat and underwing-coverts, rufous undertail-coverts. Female has shorter tail than male. Juvenile is duller, browner above with rufous areas paler, tips of tertials, inner secondaries and uppertail-coverts pale rufous, shorter tail. Race *saturatior* is darker than nominate; *monteiri* is dark, has white patches in tail. Voice. Song is rambling mix of nasal, whining and creaking notes; calls include a nasal "nyaa" contact call, a distinctive piping "pyuuuu" and a "mew" and "weh".

Habitat. Grassland, savanna, bush, woodland, especially mopane woodland, clearings in forest, rivers, cultivation, also human habitations. To c. 2800 m. Compared with *C. semirufa*, found in more wooded areas and less often near human habitation.

Food and Feeding. Diet includes Hymenoptera (flying ants), termites (Isoptera), flies (Diptera). Feeds alone or in small groups, mixes with other hirundines; attends grass fires in larger groups, up to 100 individuals. Forages 20-30 m above trees or over water; flight gliding, alternating with short periods of flapping.

Breeding. Before and during rains in W Africa, e.g. Jul-Oct and Dec in Senegambia, Jan, Apr-Jul and Oct in Ghana, May-Aug in Nigeria and Feb-Sept in Cameroon; Apr, Jul and Nov in Ethiopia; mainly in rains in E Africa, e.g. Apr-May and Dec in Kenya, Feb-Jul and Oct-Dec in Uganda, and Jan-Feb, Apr, Oct and Dec in Tanzania; Apr-Jul in DRCongo, Nov-Jan in Angola, Aug-Apr in Zambia, Aug-May in Zimbabwe, and most months in South Africa; may be double-brooded. Solitary, nests well spaced out. Nest built by both sexes, taking up to 4 weeks, retort-shaped with long tunnel entrance, made of mud, lined with grass and feathers; species sometimes builds up a hole with mud, rather than making a full nest; nest often in hole in tree, especially baobab (*Adansonia*), alternatively in riverbank, termite mound, cliff, cave, bridge, culvert, or inside or on building; old nests of own or other species often repaired and reused. Clutch 2-4 eggs, usually 3; incubation and fledging periods not documented; fledglings roost in nest, sometimes over a period lasting several weeks.

Movements. Mainly resident, especially in S; partly migratory in some areas, and often present mainly in wet season N of equator. In W Africa present mainly May-Oct in Senegambia, Feb-Aug in Togo, Mar-Jun in Benin; in Nigeria, Feb-Jul in N and Jan-May in S. In extreme S parts of range, possibly some post-breeding movement out of N Namibia and Botswana; only a breeding visitor Aug-Apr to Mashonaland (N Zimbabwe).

Status and Conservation. Not globally threatened. Generally considered to be scarce or only locally common, especially in S of range; common in some areas, e.g. Ghana, E Africa, Zambia, Zimbabwe. Has recently spread S in Zimbabwe and in NE South Africa (Kruger National Park). Utilizes artificial nesting sites to only a limited extent; when nesting in buildings, prefers those that are uninhabited.

Bibliography. Aspinwall (1980b), Bannerman (1939, 1953), Barlow *et al.* (1997), Barry (1998), Beesley (1972), Benson & Benson (1977), Benson *et al.* (1971), Borrow & Demey (2001), Britton (1980), Brooke (1984a), Brosset & Érard (1986), Brown & Britton (1980), Byaruhanga *et al.* (2001), Clancey (1964b), Dean (2000), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1973), Fishpool & Evans (2001), Ginn *et al.* (1989), Gore (1990), Grimes (1987), Harrison *et al.* (1997), Irwin (1981), Keith *et al.* (1992), Lewis & Pomeroy (1989), Louette (1981), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993a), Nikolaus (1987), Penry (1994), Pitman (1931), Salvan (1969), Sclater & Moreau (1933), Short *et al.* (1990), Sinclair & Hockey (1996), Stevenson & Fanshawe (2002), Tarboton (2001), Urban & Brown (1971), Verheyen (1953), Waugh (1978), Winterbottom (1942), Zimmerman *et al.* (1996).

70. **Red-rumped Swallow**

Cecropis daurica

French: Hirondelle rousseline **German**: Rötelschwalbe **Spanish**: Golondrina Dáurica
Other common names: Golden-rumped Swallow; Black-vented Swallow (*melanocrissus*); Ceylon Swallow, Sykes's Striated Swallow (*hyperythra*); Lesser Striated Swallow (*daurica, japonica, erythropygia*); West African Swallow/Striated Swallow, Lowland Swallow (*domicella*)

Taxonomy. *Hirundo daurica* Laxmann, 1769, Mount Schlangen, near Zmeinogorsk, Altai, Russia.

Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Forms a superspecies, and sometimes treated as conspecific, with *C. striolata* and *C. badia*, the three replacing each other geographically; race *japonica* is intermediate between former species and nominate race of present species. W & NE African race *domicella* sometimes considered a separate species; taxonomic status of Sri Lankan *hyperythra* also requires review. Proposed races *disjuncta* (from Birwa Plateau, in Sierra Leone) and *gephyra* (W Inner Mongolia S to E Tibet and Sichuan) are probably indistinguishable from, respectively, *kumboensis* and nominate. Ten subspecies currently recognized.

Subspecies and Distribution.

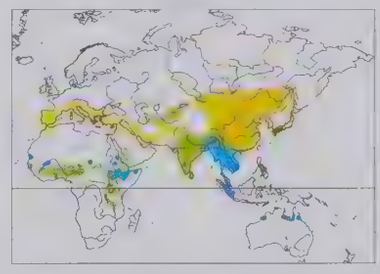
C. d. rufula (Temminck, 1835) - SW & S Europe (Iberian Peninsula, Mediterranean countries) and N Africa E to S Asia Minor, Levant (S to Israel), NE Saudi Arabia, W & S Iran, Pakistan, NW India and Tien Shan; winters Africa and SW Asia.

C. d. daurica (Laxmann, 1769) - NE Kazakhstan E to SE Russia (W Amurland) and N Inner Mongolia, S to SC China (S to N Yunnan); winters S & SE Asia.

C. d. japonica (Temminck & Schlegel, 1845) - E Amurland, NE, E & S China, Korea and Japan; winters SE Asia S to N Australia.

C. d. nipalensis (Hodgson, 1837) - Himalayas E to SE Xizang (Tibet) and N Myanmar; winters India.

C. d. erythropygia (Sykes, 1832) - India from Punjab E to West Bengal, and S; winters S India and Sri Lanka.



C. d. hyperythra (Blyth, 1849) - Sri Lanka.

C. d. domicella (Hartlaub & Finsch, 1870) - Africa from Senegambia and Guinea E to Sudan and SW Ethiopia.

C. d. kumboensis (Bannerman, 1923) - Sierra Leone (Birwa Plateau) and W Cameroon (Bamenda Highlands).

C. d. melanocrissus Rüppell, 1845 - highlands of Ethiopia and Eritrea.

C. d. emini (Reichenow, 1892) - SE Sudan, Uganda and C Kenya S to N Zambia and Malawi.

Descriptive notes. 16-17 cm; 19-29 g. Distinctive. Nominate race has glossy deep blue crown and back separated by incomplete chestnut collar, chestnut rump with fine dark streaks; wings and tail blackish with some gloss, outer tail feathers elongated; underparts buffy with long dark streaks, undertail-coverts black; underwing-coverts creamy buff. Distinguished from most other hirundines by combination of chestnut collar and rump, black undertail-coverts, absence of white in tail and of breastband; from *C. striolata* by smaller size, less heavy streaking, clearer hindcollar. Female has shorter tail than male. Juvenile is duller, browner above, rufous areas paler, streaking less distinct, wing feathers tipped buff, shorter tail. Races differ mainly in extent of streaking and colour of rump and underparts (varying from white to chestnut), and presence of collar on hindneck: *japonica* has faint streaks on rump, heavily streaked underparts, broadly interrupted collar; *nipalensis* has underparts pale rufous and well streaked, collar sometimes interrupted; *erythropygia* has dark rump, buffish-white underparts with narrow streaks, collar usually interrupted; *hyperythra* has deep rufous underparts with no or faint streaks, no distinct collar; *rufula* has pale rufous underparts, narrow streaks and complete collar; in Africa, *domicella* has white or pinkish-buff underparts with little streaking, *melanocrissus* is buffy below with small streaks only on breast, *emini* has pale rufous underparts without streaks, and *kumboensis* is intermediate between previous two. Voice. Short twittering song; calls include a contact call "djuit", a mewing territorial call, a short alarm call and an aggressive "krr" call.

Habitat. Open hilly country and mountains, river gorges, valleys, sea cliffs, cultivation, and human habitations, including towns. Sea-level to 800 m, rarely to 1600 m, in Europe; elsewhere to c. 3500 m. In non-breeding season, occurs in grassland, cultivation and forest clearings, and roosts in reedbeds.

Food and Feeding. Adult diet includes flies (Diptera), beetles (Coleoptera), bugs (Hemiptera), termites (Isoptera), Orthoptera, Hymenoptera. In a study of 25-day-old nestlings of race *rufula*, 94% of diet was flying ants, rest of diet consisting of other hymenopterans, dipterans, coleopterans and a cockroach (Blattaria); nestlings in Uzbekistan were fed on cicadas (Cicadidae) and coleopterans. Forages usually alone, in pairs or in small groups; mixes with other hirundines. Feeds both low over vegetation and high up; flight slow, with frequent gliding and soaring. Patrols cliff face or other feeding route. Sometimes feeds around human settlements and similar sites that attract insects, including markets, bazaars and shipping docks. Will perch on vegeta-

tion or ground to pick up insects, including flies from camel dung. Visits grass fires in Indian Subcontinent.

Breeding. Apr-Sept in Europe, mainly Apr-Aug in Himalayas, India and Sri Lanka, Jun-Jul in E Asia, May-Aug in Japan; in Africa, Apr-Jul in N, mainly Oct-May in W, Jan and Apr-Aug in Ethiopia and Mar-Jul in E; two broods usual, in Spain often three (21% of 65 pairs). Usually solitary, sometimes loose groups of a few pairs, rarely up to 50 pairs and one record of 100; nests in groups sometimes clustered, but often dispersed (2-3 m apart) as pairs aggressive towards each other, e.g. one group of four had nest entrances at least 29 cm apart; record of eight nests in different rooms of a building. Displaying male circles, with calling, around female, if she perches he may perch nearby and sing, sometimes displaying tail. Nest built by both sexes, taking 1-2 weeks, enclosed, with tunnel entrance, made of mud pellets, sometimes with a little dry grass admixed, lined with mixture of white feathers, hair, plant down, leaves, pine (*Pinus*) needles or dry grass; nest of *Hirundo rustica* sometimes taken over and built up; placed 0·5-20 m above ground, usually 2-4·5 m (1·5-4·3 m when on a bridge), usually affixed to underside of horizontal surface of natural or artificial site, e.g. cliff, rock face, cave, culvert, bridge, drainage pipe, military bunker, bus shelter, verandah, under eaves or in stairwell or corridor of building, unoccupied farm building; nests reused in same and successive seasons. Clutch size varies regionally, 2-7 eggs (mainly 4-5) in Europe, 5 or 6 in Siberia, generally 3 or 4 (occasionally 5) in Asia but only 2 or 3 in Sri Lanka, and 2-3 in Africa; of 135 clutches in Spain, 46% were of 4 eggs, 29% of 5, 15% of 3, 5% of 2, 4% of 6, 1% of 7; also seasonal decline, e.g. in Spain mean size of first clutch 4·51, of second 3·8, of third 3·6; incubation by both sexes, female doing more, starts from last egg, period 11-16 days, mostly 14-15 days; chicks fed by both parents, more by female in later stages, in Spain 53 nest visits per day at 3 days, 72 at 8 days, 138 at 13 days, 82 at 18 days, and in Bulgaria hourly feeding rate 9·4 on day 5, 22·8 on day 10, 24·5 on day 15; nestling period 26-27 days, but as few as 20 days recorded; fledglings fed by parents for at least 5-6 days, remain with them for 8-9 days, and roost in nest for 2-3 weeks after fledging. Breeding success in Spain 74·4%, average 6·38 fledglings per pair per season; nests often usurped by House Sparrow (*Passer domesticus*) and sometimes by White-rumped Swift (*Apus caffer*). Oldest recorded bird c. 8 years.

Movements. Migratory in N parts of range, but mostly resident in S. Forms small post-breeding flocks of tens or hundreds of birds, often with other hirundines and swifts (Apodidae). Present on N breeding grounds mainly during period Mar/Apr-Sept/Oct; individual winter ranges unclear, as races overlap and are difficult to distinguish in field, but together extend from Africa across to SE Asia and S recently to N Australia. Migrants recorded across N Africa, but rare in Tunisia and Libya; European and W Asian breeders presumed to winter in savanna belt of N Afrotropics; those from Spain and Morocco may winter on W side and those from SE Europe and SW Asia on E side. Pronounced passage across Strait of Gibralter in Apr and Sept and through E Mediterranean in Mar-Apr and Sept. E Asian races (nominate, *japonica*) recorded in winter from Nepal and NE India E to SE Asia, but only scarce in areas S from Indochina and W Malaysia; first recorded in N Australia in 1983, presumably *japonica* (one confirmed as such). Older birds return to breeding grounds singly or in pairs, and arrive before younger individuals. Largely resident in Africa, India, Sri Lanka and parts of S China and Japan, but some post-breeding movements in e.g. Sudan and Nigeria and occurs seasonally in some E African localities; Himalayan *nipalensis* moves to lower altitudes after breeding. Frequent vagrant outside range, e.g. in Europe N to British Is (regular since 1964), Netherlands, Poland, Scandinavia and Iceland, and in Atlantic Ocean on Azores and Canary Is.

Status and Conservation. Not globally threatened. Common in most of range; uncommon to locally common in W Africa; rather local in E Africa, where occurs in several protected areas in Tanzania. Population sizes poorly known; estimated at perhaps 63,000 pairs in Europe, where majority of population in Iberia and Balkan Peninsula. Is extending its range and increasing its use of artificial nest-sites, although less dependent on them than is *Hirundo rustica*; common in towns in sub-Saharan Africa, but in some parts of range, e.g. Pakistan, nests mainly on natural rock faces. In Israel has spread since 1960s from mountainous areas to lowland settlements. Range in Europe has extended N since 1920s in Iberia (now frequently nests on bridges) and since c. 1950s in Balkans; first bred C Spain 1951-1953, N Spain 1960, Corsica 1962, mainland France 1965, Sardinia 1965, Romania 1975, and recently bred in Slovenia; large expansion 1970-1990 in Portugal, Bulgaria and Romania, and smaller expansion in France since 1980s. In Japan has extended range N since 1950s, into N Honshu and Hokkaido.

Bibliography. 71. Striated Swallow

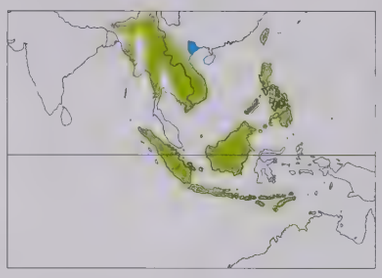
Cecropis striolata

French: Hirondelle striolée **German**: Strichelschwalbe **Spanish**: Golondrina Estriada
Other common names: Eastern Red-rumped Swallow, Greater/Larger Striated Swallow, Mosque(!)/Oriental Mosque Swallow

Taxonomy. *Hirundo striolata* Schlegel, 1844, Java.

Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Forms a superspecies with *C. daurica* and *C. badia*, the three replacing each other geographically; sometimes treated as conspecific with former, race *japonica* of which is intermediate between nominate race of that species and present species; often considered conspecific also with *C. badia*, but recent review suggests that they are separate species. Four subspecies recognized.



Subspecies and Distribution.

C. s. mayri (B. P. Hall, 1953) - NE Bangladesh, NE India, N Myanmar and S China (SW Yunnan); winters N, E & S Myanmar, NW Thailand and Vietnam (E Tonkin, C Annam).

C. s. stanfordi (Mayr, 1941) - N, E & S Myanmar, NW & NE Thailand, Laos, Cambodia, C & S Annam and Cochinchina.

C. s. vernayi (Kinnear, 1924) - S Myanmar (N Tenasserim) and W Thailand.

C. s. striolata (Schlegel, 1844) - Taiwan, Philippines, Greater Sundas, and Lesser Sundas E to Wetar and Timor.

Descriptive notes. 19 cm; 22 g. Nominate race has crown and back glossy steel-blue, rufous hindcollar poorly defined or absent; rump chestnut with narrow streaks, shorter uppertail-coverts chestnut, longer ones black with blue gloss; wings and tail blackish-brown with slight blue gloss, tail deeply forked; cheeks white with sepia streaks, underparts white with heavy streaking, densest on chin and throat; undertail-coverts blackish-brown; underwing-coverts white with buffy wash. Differs from *C. daurica* in larger size, heavier streaking, lack of clear collar; from *C. badia* in smaller size, whiter and more streaked underparts. Sexes alike. Juvenile is duller than adult, browner above, rufous areas paler, buff tips of wing-coverts and tertials, shorter tail. Races differ mainly in extent of streaking and colour of underparts: *mayri* has broader streaks than nominate; *stanfordi* is as broadly streaked as previous, has well-defined black area near thighs; *vernayi* has rusty chestnut wash on underparts. Voice. Song is a soft twittering; calls include a "pin" or "quitsch" uttered in flight.

Habitat. Open hilly country, river gorges, forest clearings, cultivation, and human habitations. To c. 2560 m.

Food and Feeding. Diet includes dipteran flies (such as mosquitoes) and cicadas (Cicadidae). Feeds alone or in small groups, sometimes with other hirundine species. Flies slowly, low over ground or along cliff face, but sometimes very high in air.

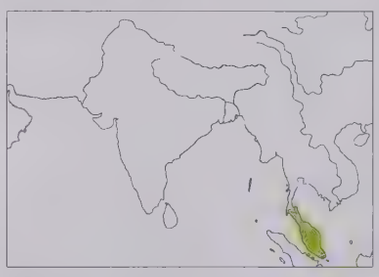
Breeding. Apr-Jul. Solitary or in small, loose groups. Nest-construction can take several weeks, nest enclosed, with long tunnel, made of mud pellets, lined with dry grass and a few feathers; attached to horizontal surface on rock face, cave roof, bridge, culvert, in house close to ceiling, under eaves of building, or on verandah. Clutch 3-5 eggs, usually 4; no information on incubation and fledging periods.

Movements. Largely resident in E & S (nominate race and *vernayi*). Elsewhere perhaps a partial migrant; NW race (*mayri*) has been recorded in non-breeding season farther S in E & S Myanmar, NW Thailand and Vietnam (E Tonkin and C Annam), and *stanfordi* in Tonkin.

Status and Conservation. Not globally threatened. Common in SE Asia, where possibly more widespread than is indicated by confirmed breeding records; locally common in Philippines; generally common in China (SW Yunnan) and Taiwan. Uncommon in Sundas, occurs in Baluran National Park, in E Java; status on Borneo uncertain. Rare in Bangladesh and NE India, where very few recent records, but possibly overlooked owing to confusion with *C. daurica*. In areas where common, has benefited from presence of artificial nest-sites such as bridges.

Bibliography. Ali & Ripley (1987), Allen (1948), Carter (2000), Coates (1990), Coates & Bishop (1997), Duckworth *et al.* (1999), Étchécopar & Hüe (1983b), Finch (1983), Gregory *et al.* (1996), Grimmett *et al.* (1998), Jones *et al.* (1994), Kennedy *et al.* (2000), Kotagama (1985), MacKinnon & Phillipps (1993, 2000), van Marle & Voous (1988), Mayr (1944), Ripley (1982), Robson (2000), Smythies (1986, 1999), Stepanyan (1995), Strange (2001), Tsai Hangyeh (1985), Vaurie (1951b), White & Bruce (1986).

72. Rufous-bellied Swallow



Cecropis badia

French: Hirondelle baie **German**: Thaischwalbe **Spanish**: Golondrina Ventrirrufa

Taxonomy. *Cecropis badia* Cassin, 1853, Malacca, West Malaysia.

Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Forms a superspecies with *C. daurica* and *C. striolata*, the three replacing each other geographically; often treated as conspecific with those, especially latter, but recent review suggests that they are separate species. Monotypic.

Distribution. Malay Peninsula.

Descriptive notes. 19-20 cm. Has crown and back glossy steel-blue, rufous hindcollar poorly defined or absent, rump unstreaked chestnut; wings and tail blackish-brown with slight blue gloss, tail deeply forked; underparts and underwing-coverts deep rufous with faint streaking. Distinguished from *C. striolata* by larger size, redder underparts, less streaking. Sexes alike. Juvenile is duller than adult, browner above, rufous areas paler, shorter tail. Voice. Song is a soft twittering or warble; also makes a single "tweep" or "pin", a sharp "cheenk", and a trembling "schwirrrr"; alarm call is a repeated "chi-chi-chi".

Habitat. Open hilly country, rocky outcrops. Forages over open country and forest. Occasionally seen around isolated buildings.

Food and Feeding. Dietary details not known; probably similar to those for *C. daurica* and *C. striolata*. Often feeds in flocks with other swallows.

Breeding. Eggs and nestlings recorded in Jun. Solitary. Nest enclosed, with long tunnel, made of mud pellets, lined with dry grass and few feathers, attached to horizontal surface on rock face. Clutch of 2 eggs recorded; no further information.

Movements. Resident.

Status and Conservation. Not globally threatened. Common. Relatively poorly known species, chiefly because it was until recently treated as a race of *C. striolata* or of more widespread and better-studied *C. daurica*.

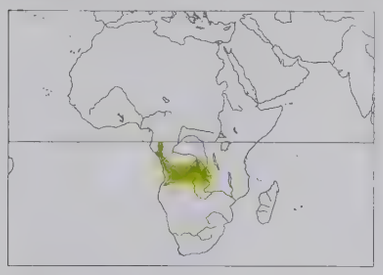
Bibliography. Allen (1948), Dickinson & Dekker (2001b), Hawa (1985), Jeyarajasingam & Pearson (1999), Madoc (1976), Medway & Wells (1976), Riley (1938), Robinson (1927), Vaurie (1951b), Wells (1990).

PLATE 69 ➤

PLATE 69

inches 3

cm 8



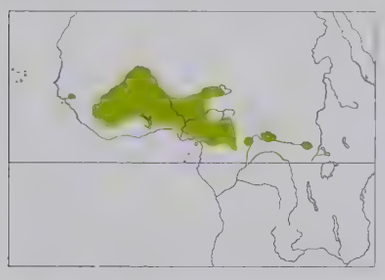
Genus *PETROCHELIDON* Cabanis, 1850

73. Red-throated Swallow

Petrochelidon rufigula

French: Hirondelle à gorge fauve **German**: Rotkehlschwalbe **Spanish**: Golondrina Gorgirroja
Other common names: Angola/Red-throated Cliff Swallow, (Angolan) Rock Swallow

Taxonomy. *Hirundo rufigula* Bocage, 1878, Caconda, Angola.
Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Forms a superspecies with *P. preussi*, and has been considered conspecific, but distinct plumage differences exist between them. Also, sometimes considered conspecific with *P. spilodera*. Monotypic.
Distribution. Gabon and S PRCongo S to C Angola, thence E to S DRCongo and NW Zambia.



Descriptive notes. 12 cm; c. 16 g. Has crown and upperparts glossy deep blue, hindneck and mantle with faint white streaks, rump rufous; wings and tail blackish-brown, tail slightly forked, white patches on inner webs of rectrices (except central pair); chin, throat and upper breast rufous, lower breast, abdomen, flanks and underwing-coverts buff, shorter undertail-coverts rufous, longer ones black with buff edges. Differs from *P. spilodera* in smaller size, blue (not rufous) forehead, plain rufous throat. Sexes alike. Juvenile is duller, browner, with rufous areas paler, pink wash on abdomen. Voice. Twittering song; harsh "tre-tre-tre" uttered in flight.
Habitat. Open grassland and cultivation, often near water and cliffs; locally also at bridges over large forest rivers. Lowlands.
Food and Feeding. Diet includes flies (Diptera). Forages usually in flocks, often with other hirundines and swifts (Apodidae), up to 30 km from nest-site. Flight fluttery and slow, with frequent gliding.
Breeding. Jul-Oct in Angola, Apr and Jun in DRCongo and Apr and Sept-Oct in Zambia. Colonies of tens or hundreds of pairs, up to c. 400, nests abutting each other. Nest enclosed, with short tubular entrance, made of mud pellets, lined with grass, placed mainly under bridge or other artificial structure, less often in natural site (cliff face, cave). Clutch 1-3 eggs; no information on incubation and fledging periods. Nests sometimes taken over by White-rumped (*Apus caffer*) and Little Swifts (*Apus affinis*).
Movements. Mainly resident or partial migrant; migratory in SE, occurring in Zambia Apr to early Dec.
Status and Conservation. Not globally threatened. Locally common. First colonized Gabon in late 1970s, continuing to expand N there; appears to be extending range also in Zambia. Expansion probably result of increased availability of nest-sites; spread into S Gabon followed construction of bridges.
Bibliography. Aspinwall & Beel (1998), Bannerman (1953), Benson (1982), Benson *et al.* (1971), Borrow & Demey (2001), Bowen (1978, 1979a), Brosset & Érard (1977), Cannell (1968), Chapin (1953), Christy (1984), Christy & Clarke (1994), van Daele (1999), Dean (1974, 2000), Dowsett (1989), Dowsett & Dowsett-Lemaire (1980, 1991, 1993, 1997), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Hall (1960), Keith *et al.* (1992), Lippens & Wille (1976), Mackworth-Praed & Grant (1963, 1973), Pedersen (2000), Taylor (1979a), Tree (1964).

74. Preuss's Swallow

Petrochelidon preussi

French: Hirondelle de Preuss **German**: Rostschläfenschwalbe **Spanish**: Golondrina de Preuss
Other common names: Preuss's Cliff Swallow

Taxonomy. *Lecythoplastes preussi* Reichenow, 1898, Sanaga River near Edéa, Cameroon.
Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Forms a superspecies with *P. rufigula*, and has been considered conspecific, but distinct plumage differences exist between them. Monotypic.
Distribution. Guinea-Bissau, Sierra Leone, NE Guinea and S Mali E to Nigeria, Cameroon and SW & S Central African Republic, also NW & NE DRCongo.

Descriptive notes. 12 cm; 12-14 g. Has glossy deep blue crown and ear-coverts, rufous patch behind eye, upperparts glossy deep blue with grey-white streaks, rump creamy buff; wings and tail blackish-brown, tail slightly forked, white patches on inner webs of rectrices (except central pair), patches small or sometimes absent on outer pair; throat, cheeks and underparts, including underwing-coverts, buff. Differs from somewhat similar *Delichon urbicum* in darker, buffier rump and underparts, white in tail, rufous on head. Sexes alike. Juvenile is duller than adult, browner, chin to breast pinkish-brown, abdomen white with pinkish wash, undertail-coverts grey-brown. Voice. Noisy twittering song; a "prrp-prrp" uttered in flight and a "pseep" alarm call.
Habitat. Savanna and cultivation, usually near cliffs and rivers.
Food and Feeding. Diet includes Hymenoptera (flying ants). Feeds in often large flocks; mixes with other hirundines and swifts (Apodidae). Forages sometimes low down, but also very high up; flight slow and fluttery, with much gliding.
Breeding. At end of dry season, mainly Feb-Jun; Nov-Jul in Mali; May-Jun, Dec-Jan and probably also Feb-Apr in Ghana; Feb-Jul in Togo and Nigeria. Colonies of tens to thousands of pairs, up to c. 2500, sometimes divided into smaller clusters, nests closely packed and abutting one another. Nest-building by both sexes, can start several weeks before eggs laid, nest bottle-shaped, enclosed, with long, tubular, downward-curving entrance, made of mud pellets, lined with grass, seeds and feathers; usually underneath horizontal surface, often over water, on rock, cliff, culvert, dam, mine shaft, bridge or building; large colonies sited particularly on bridges. Clutch 2-3 eggs; incubation and fledging periods not documented. Nests over rivers sometimes destroyed by floods.
Movements. Resident or partial migrant. Forms large flocks and disperses after breeding. Movements poorly known; irregular in Nigeria, in N present only in rains; absent Aug-Dec in Togo. Does not return to same areas to breed each year.
Status and Conservation. Not globally threatened. Rare to locally common; irregularly distributed. May have benefited from creation of new artificial nest-sites, such as culverts and bridges, which are readily used. Has apparently recently extended range into Sierra Leone, although possibly previously overlooked there.
Bibliography. Ash *et al.* (1989), Ashford (1968), Bannerman (1939, 1953), Bannerman & Bates (1926), Borrow & Demey (2001), Broadbent (1969b), Chapin (1953), Cheke & Walsh (1996), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fishpool & Evans (2001), Gatter (1997), Germain *et al.* (1973), Grimes (1987), Jourdain & Shuel (1935), Keith *et al.* (1992), Lamarche (1981), Louette (1981), Mackworth-Praed & Grant (1973), Pedersen (2000), Serle (1940, 1965), Tye (1985).

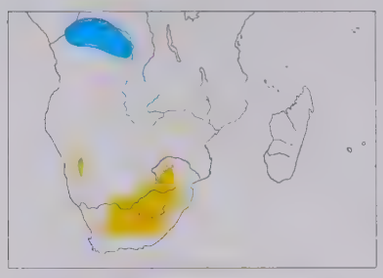
75. Red Sea Swallow

Petrochelidon perdita

French: Hirondelle de la Mer Rouge **Spanish**: Golondrina del Mar Rojo
German: Rotmeerschwalbe
Other common names: Red Sea Cliff Swallow

Taxonomy. *Hirundo perdita* Fry and D. A. Smith, 1985, Sanganeb lighthouse, Red Sea north-east of Port Sudan, Sudan.
Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Forms a superspecies with *P. spilodera*. Monotypic.
Distribution. Unknown; possibly breeds in Red Sea hills of Sudan or Eritrea, or in coastal hills of W Saudi Arabia (N of Jedda).

Descriptive notes. c. 14 cm. Has forehead and lores blackish, crown blue-black, back glossy deep blue, rump grey-white; wings and tail blackish-brown, tail square-ended; chin with white spot, throat and upper breast bluish-black, rest of underparts off-white, buffy undertail-coverts; underwing-coverts white. Differs from *P. spilodera* in colour and pattern of head to breast, grey rump. Juvenile unknown. Voice. Unknown.
Habitat. Unknown; possibly open grassland, mountainous areas, cliffs, as for other members of genus.
Food and Feeding. Unknown. Unidentified swallows, possibly of this species, observed in Ethiopia were feeding over grassland with other hirundines, and along cliffs; flight fluttering, with frequent turns.
Breeding. Unknown. Single specimen, found in May, appeared to have completed moult, suggesting possible breeding in early part of year.
Movements. Unknown.
Status and Conservation. Not globally threatened. Data-deficient. Known only from single type specimen, found dead in May 1984. Range unknown. Unidentified hirundines recorded several times in Ethiopia (e.g. 20 at L Langano, up to 12 in Awash National Park, also at three other sites) were possibly of this species or, perhaps more likely, belonged to another, as yet undescribed taxon; features included whitish (not blue-black) throat and upper breast, dark (not pale) chin, and buffy to pale rufous (not grey) rump. Otherwise, two pale-rumped swallows seen at sea as they flew towards Jedda may also have been of present species.
Bibliography. Atkins & Harvey (1994), Collar & Andrew (1988), Collar *et al.* (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Fry & Smith (1985), Keith *et al.* (1992), Madge & Redman (1989), Sinclair & Ryan (2003), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Vuilleumier *et al.* (1992).



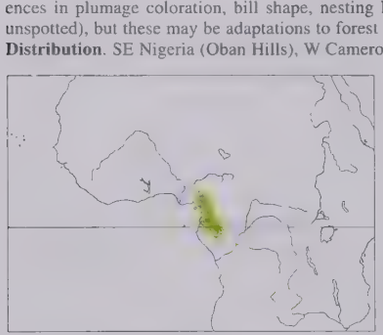
76. South African Swallow

Petrochelidon spilodera

French: Hirondelle sud-africaine **German**: Klippenschwalbe **Spanish**: Golondrina Sudafricana
Other common names: South African Cliff Swallow

Taxonomy. *Hirundo spilodera* Sundevall, 1850, Valsch River, Free State, South Africa.
Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Forms a superspecies with *P. perdita*. Sometimes considered conspecific with *P. rufigula*. Monotypic.
Distribution. Breeds Namibia, Zimbabwe, South Africa (Eastern, Free State and E Cape Provinces, also NW KwaZulu-Natal); migrates N to SE PRCongo and W DRCongo.
Descriptive notes. 14 cm; 16-26 g. Has pale rufous forehead and lores, dark brown crown, black head side and hindneck; upperparts deep blue-black, whitish streaks on mantle, rump pale rufous; wings and tail blackish-brown, tail square-ended; throat pale rufous to whitish, variable amount of dark speckling; underparts variable, usually rufous on breast and undertail-coverts, whitish on belly and flanks, with varying amount of dark speckling on upper breast and of streaking elsewhere; underwing-coverts pale rufous. Sexes alike. Juvenile is duller, with rufous areas paler. Voice. No clear song; calls are a warbling chatter call, a threat call which is a harsher version of the chatter call, a nest-relief call, low- and high-intensity alarm calls, a distress call and a whistle-like contact call.
Habitat. Open grassland, lightly wooded savanna and semi-arid karoo.

On following pages: 77. Forest Swallow (*Petrochelidon fuliginosa*); 78. Streak-throated Swallow (*Petrochelidon fluvicola*); 79. Fairy Martin (*Petrochelidon ariel*); 80. Tree Martin (*Petrochelidon nigricans*); 81. Cliff Swallow (*Petrochelidon pyrrhonota*); 82. Cave Swallow (*Petrochelidon fulva*); 83. Chestnut-collared Swallow (*Petrochelidon rufocollaris*).



Food and Feeding. Diet includes beetles Coleoptera (especially Scarabaeidae and Curculionidae), dipterans (especially Muscidae and Drosophilidae), bugs (Hemiptera), Hymenoptera (flying ants and parasitic wasps), lepidopterans, termites (Isoptera) and spiders (Araneae); flightless prey include carabid beetles, beetle and moth larvae, termites, spiders. Forages alone or in flocks of 10-50, sometimes with other hirundines. Feeds at range of heights, often high up, but in one study at average of 2 m above ground. Flight fast, with short glides when foraging. Hovers over bushes to flush insects, also feeds around other animals, follows plough and visits bush fires. Recorded as feeding on ground and from vegetation more often than do other hirundines.
Breeding. Sept-Apr; two or three broods reported for small proportion of pairs. Colonies of a few tens to several hundreds of pairs, up to c. 1300 recorded, sometimes mingled with Little Swift (*Apus affinis*) colonies; nests often abut one another; defends area around nest entrance. Male starts to build ledge for nest, crouches on nest and sings to attract mate, displays tail and quivers wings when female perches; copulation at nest-site. Nest-building by both sexes, can take a week, nest enclosed, with short, downward-facing tubular entrance near top, made of mud pellets, lined with grass, wool, plant down or, less often, feathers, latter brought throughout incubation; placed high up on vertical surface or below overhang, often over water, almost always in artificial site such as eaves of building, bridge, culvert, water tank or quarry, rarely in natural site (cliff); crevice sometimes used, then mud added and entrance tunnel made; also, nests from previous years repaired and reused. Clutch 1-4 eggs, normally 3, number decreasing during course of season; brood parasitism by conspecifics (16% of nests in one study) may account for some clutches of 4; incubation by both sexes, average bout length 9 minutes, period 14-16 days, mean 14·6 days; nestlings fed by both parents, rate of 2-9 feeds per nestling per hour, fledging period 24-25 days. Success rate from egg to fledgling 49% in one study, 57% in another; causes of nest loss include attacks by the red ants *Techmomyrmex albipes* and *Acantholepis capensis* (in one case leading to colony being abandoned), predation by monitor lizards (*Varanus*) and humans, egg removal and expulsion of adults by sparrows (*Passer*), and nest parasites such as louse-flies (*Ornithomya*), ticks (*Ornithodoros*) and mites (*Macronyssus*); nests also taken over by White-rumped (*Apus caffer*) and Little Swifts (*Apus affinis*).
Movements. Migratory. Highly gregarious after breeding. Present on breeding grounds in S Aug-Apr, a few remaining all year; migrates N to SE PRCongo and W DRCongo, where present Apr-Sept; probably passes through Botswana, Namibia, Angola and W Zambia on migration. Males return to breeding sites earlier than females. Vagrant in Malawi and C & SE Gabon.
Status and Conservation. Not globally threatened. Generally common in suitable habitat in main breeding range in South Africa; less common and more irregular in Namibia, Botswana, Zimbabwe and Lesotho. Has used artificial sites for nesting for over 100 years, and has benefited from increased availability of, especially, bridges and culverts; for example, construction of new towns and bridges allowed expansion into E Cape. Range has expanded N into Zimbabwe, where bred near Bulawayo for a few years and then in NE (Headlands District); also expansion W in Cape Province during and after wet summer of 1961-1962. Regularity of breeding in Karoo unclear, as observations sporadic. Suffers nest competition from House Sparrow (*Passer domesticus*) and Cape Sparrow (*P. melanurus*). Nests sometimes destroyed and nestlings taken for food by humans.

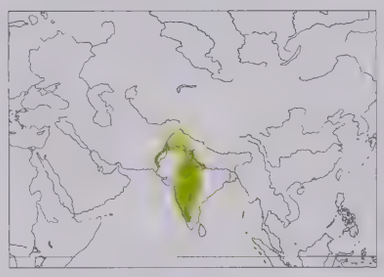
77. **Forest Swallow**

Petrochelidon fuliginosa

French: Hirondelle de forêt **German**: Bronzeschwalbe **Spanish**: Golondrina Selvática
Other common names: Forest Cliff Swallow, Dusky Swallow/Cliff Swallow

Taxonomy. *Lecythoplastes fuliginosus* Chapin, 1925, Lolodorf, southern Cameroon.
Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Affinities of present species unclear; has been considered distinct from others of genus on account of differences in plumage coloration, bill shape, nesting habits (solitary), nest shape and eggs (usually unspotted), but these may be adaptations to forest environment. Monotypic.
Distribution. SE Nigeria (Oban Hills), W Cameroon, Equatorial Guinea and Gabon.



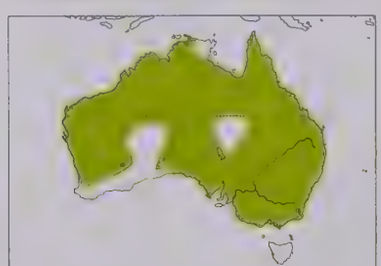
Descriptive notes. 11 cm. Plumage is almost entirely blackish-brown; crown black with blue gloss, chin and throat rusty brown; tail slightly forked. Distinguished from most *Psalidoprocne* species mainly by tail shape, from very similar *Psalidoprocne nitens* by rusty tinge on throat. Sexes alike. Juvenile apparently resembles adult. Voice. Not very vocal; soft song; also a "wheet" uttered in flight and a "pitchri".
Habitat. Lowland forest; forages in open areas, clearings, and around villages.
Food and Feeding. Details of diet not known. Feeds usually in pairs or small groups, sometimes with other swallows. Flight fast and fluttering, with frequent gliding.
Breeding. Poorly known. Eggs in Apr-Jun and young in Jan and Nov in Cameroon; immature in Jul in Gabon. Apparently solitary, but few records. Nest built by both sexes, completion in one case taking 2 weeks, enclosed, with long tubular entrance (one nest had two entrances), made of mud pellets, lined with vegetable fibres; attached to rock overhang, cave wall, or ceiling of building or verandah, probably sometimes also to tree. Clutch 2-3 eggs; no information on incubation and fledging periods.
Movements. Probably largely sedentary. Apparently an irregular migrant in Gabon; passage individuals recorded in Jan and Mar, and immature in Jul. Vagrant in NW PRCongo.
Status and Conservation. Not globally threatened. Restricted-range species: present in Cameroon and Gabon Lowlands EBA. Status unclear, as poorly known. Not uncommon in Cameroon; rare in Oban Hills Forest Reserve, in Nigeria.
Bibliography. Ash (1990), Bannerman (1951), Borrow & Demey (2001), Brosset & Érard (1986), Chapin (1925, 1948), Christy & Clarke (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Earlé (1987e), Elgood *et al.* (1994), Fishpool & Evans (2001), Hall & Moreau (1970), Keith *et al.* (1992), Louette (1981), Morel & Morel (1990), Serle (1954), Voisin (1958).

78. **Streak-throated Swallow**

Petrochelidon fluvicola

French: Hirondelle fluviatile **German**: Braunscheitelschwalbe **Spanish**: Golondrina India
Other common names: Indian Swallow/Cliff Swallow/Cliff Martin

Taxonomy. *Hirundo fluvicola* Blyth, 1855, Somar and Kane Rivers, Bundelkund, northern Madhya Pradesh, India.
Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. May form a superspecies with *P. ariel*, and sometimes considered conspecific. Monotypic.
Distribution. NE Afghanistan, C & E Pakistan (mainly R Indus plain) and NW & C India (E to E Uttar Pradesh, S to S Karnataka).



Descriptive notes. 11-12 cm; 8-12 g. Has forehead, crown and nape dull chestnut with faint dark streaks, back glossy deep blue with few narrow whitish streaks, rump pale brown; wings and tail blackish-brown, tail almost square-ended; underparts buffy white, blackish-brown streaks on, especially, chin, throat, neck side and breast; underwing-coverts grey-brown. Distinguished from very similar *P. ariel* by brighter crown, streaked neck side. Sexes alike. Juvenile is duller and browner than adult, with buff feather edges, faint streaks on underparts. Voice. Song is a twittering; also a sharp "trr trr".
Habitat. Open country, foothills, cultivation, and human habitations, including towns; often near water, including canals, rivers, lakes. To c. 1000 m, mostly below 700 m; occasionally higher on passage.
Food and Feeding. Diet includes flies (Diptera). Forages in flocks; joins other hirundines. Flight weak, fluttery.
Breeding. Varies locally; mainly Mar-Jun in N and Dec-Apr and Jul-Oct in S; peaks Mar-Apr and also Jul-Oct in Pakistan; may have two broods. Colonial, a few tens to a few hundred pairs, nests abutting each other, often in tiers. Nest built by both sexes, enclosed, with tubular entrance, made of mud pellets, lined with dry grass, horsehair and feathers, attached to cliff, bridge, culvert, irrigation barrage, or building (deserted or inhabited); sites over water preferred. Clutch 3-4 eggs, occasionally 2; both sexes incubate and both feed nestlings, incubation and fledging periods not documented.
Movements. Mainly resident; some post-breeding movements, especially to lower altitudes, e.g. winter visitor Oct-Mar to Goa (SW India). Mainly a breeding visitor in Afghanistan, N Pakistan and NW India, although some reported to be resident in N Pakistan. Scarce visitor to Nepal, and several records outside main Indian range (e.g. E to Bihar and Orissa, W to Gujarat). Vagrant in Bangladesh and Sri Lanka.
Status and Conservation. Not globally threatened. Common in Pakistan, locally common in India. Has probably benefited from increased availability of artificial nest-sites associated with human habitations; for example, apparent increase in numbers in Punjab with expansion of irrigation systems and canal bridges. In Pakistan, appears also to have spread S into N Sind during last century.
Bibliography. Ali (1996), Ali & Ripley (1987), Daniels (1997), Grimmett *et al.* (1998), Harrison, J. (1999), Henry (1998), Hüe & Étchécopar (1970), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), King (1997), Lamsfuss (1998), Mahabal & Lamba (1987), Majumdar *et al.* (1992), Mukherjee (1995), Phillips (1978), Ripley (1982), Roberts (1992), Stuart Baker (1934), Vaurie (1951b, 1959), Wijesinghe (1994).

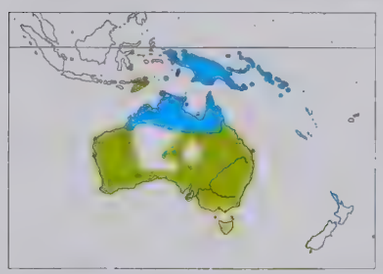
79. **Fairy Martin**

Petrochelidon ariel

French: Hirondelle ariel **German**: Arielschwalbe **Spanish**: Golondrina Ariel

Taxonomy. *Collocalia Ariel* Gould, 1843, New South Wales, Australia.
Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. May form a superspecies with *P. fluvicola*, and sometimes considered conspecific. Birds from NW Australia described as race *conigravi*, but indistinguishable from those in rest of range. Monotypic.
Distribution. Australia (excluding Melville I, Groote Eylandt, much of SW, and Tasmania).

Descriptive notes. 11 cm; 9-14 g. Has forehead, crown and nape rufous-brown, face grey-brown, back glossy deep blue with few whitish streaks, rump dull white or buffish-white; wings and tail brownish-black, tail slightly forked; underparts dull white, fine streaks on throat and upper breast, grey-white undertail-coverts; underwing-coverts white, tinged brown. Distinguished from very similar *P. fluvicola* by somewhat duller crown, plainer unstreaked face, from *P. nigricans* by rufous (not blue) crown and nape. Sexes alike. Juvenile is duller, browner, with buffy feather edges. Voice. Song is a high-pitched twittering; contact call "chrrr" or "prrrt-prrrt".
Habitat. Open areas, such as open woodland and grassland, usually near water.



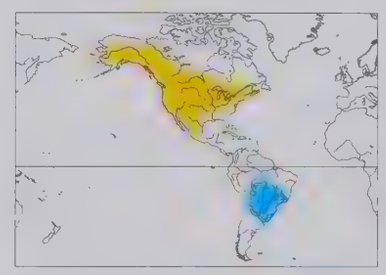
Food and Feeding. Diet includes mayflies (Ephemeroptera), termites (Isoptera), bugs (Hemiptera), beetles (Coleoptera), flies (Diptera), hymenopterans (including parasitic wasps and ants) and moths (Lepidoptera). Forages in flocks; flight slow, usually high up. Also recorded as feeding on moths on a lawn.
Breeding. Aug-Feb; two broods, sometimes three. Socially monogamous, but some extra-pair paternity (in one study, 29% of 70 broods and 14% of nestlings). Colonies, usually of a few tens of pairs (8-30 in one study), sometimes to several hundred pairs, nests built close together; breeding asynchronous within and between colonies. Nest-construction by both sexes, average times in two studies 15 and 30 days, nest enclosed, with tube entrance, made of mud pellets, lined with grass and feathers; attached mainly to artificial site such as culvert, bridge, mine shaft, pipe, wharf, verandah or under house eaves, less often cliff, cave, riverbank or tree, and usually over water. Clutch 2-5 eggs, average in studies in Victoria and New South Wales 3·5; incubation by both sexes, 45% by male, period in Victoria 12-18 days (mean 13·7), in New South Wales 11-17 days (mean 13·8); both also feed nestlings, fledging period in Victoria 17-32 days (mean 22·1), in New South Wales 14-30 days (mean 22·5), duration increasing with larger brood size. Success in Victoria 1·8 fledglings per complete clutch, pairs produced 0-8 fledglings per season, in New South Wales brood size 3·3 early in season and 3 late in season; failure rate high during prolonged cold, wet weather through parents deserting nest, adult mortality also occurs in such conditions; other causes of failure include nest falling down, flooding, nest predation by kingfishers (Alcedinidae), and competition with House Sparrow (*Passer domesticus*), Zebra Finch (*Taeniopygia guttata*) and pardalotes (*Pardalotus*).
Movements. Some post-breeding movements. Partial migrant in SE Australia; large movement to N parts of Australia after breeding. Adults, especially males, generally return to same breeding site in successive years. Recorded N to islands in Torres Strait, Lesser Sundas and New Guinea, in S in Tasmania, and in New Zealand.
Status and Conservation. Not globally threatened. Widespread and common, especially in E. May have benefited from increased availability of artificial nest-sites and increase in amount of grassland habitat over the last century. Was fairly regular breeder in Tasmania in 19th century, and unoccupied nest found there in 1968. Several sightings in New Zealand in past few decades, with a few possible records of breeding (e.g. nests found in 1977/78 and a family group in 1983).
Bibliography. Baldwin (1965), Beehler *et al.* (1986), Bell (1968, 1984), Blakers *et al.* (1984), Coates (1990), Coates & Bishop (1997), Finch (1982), Gregory (1994, 1995), Hamilton (1981), Heather & Robertson (1997), Inskipp *et al.* (1996), King (1997), Lane (1965), Lord (1956), Macdonald (1988), Magrath (1998, 1999), Magrath & Elgar (1997), Magrath *et al.* (2002), Morcombe (2000), Murray *et al.* (1987), Nevill (1984a), Pizzey & Knight (1997), Reilly & Garnett (1973), Riddell & Taylor (1984), Robertson & Heather (2001), Schodde & Mason (1999), Sedgwick (1958), Semmens (1993), Serventy & Whittell (1962), Simpson & Day (1998), Slater *et al.* (1989), Tarburton (1991), Trounson & Trounson (1987), Vincent (1972), White & Bruce (1986).

80. Tree Martin

Petrochelidon nigricans

French: Hirondelle des arbres **German**: Baumschwalbe **Spanish**: Golondrina Arborícola
Other common names: Australian Tree Martin

Taxonomy. *Hirundo nigricans* Vieillot, 1817, Hobart, Tasmania.
Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Affinities of species not clear, as it differs from typical members of genus in e.g. nest structure and material. Until recently, W mainland population was placed in nominate race, but all those in Australia now thought to belong to race *neglecta*, differentiated from Tasmanian population. Three subspecies recognized.
Subspecies and Distribution.
P. n. timoriensis Sharpe, 1885 - E Lesser Sundas (Timor, probably also Flores).
P. n. neglecta Mathews, 1912 - Australia (except N and dry C areas).
P. n. nigricans (Vieillot, 1817) - Tasmania; migrates N as far as New Guinea.



Descriptive notes. 13 cm; 14-19 g. Nominate race has rufous forehead band, glossy deep blue crown, nape and back, dull white rump with brownish-black shaft streaks, dusky uppertail-coverts with pale feather margins; wings and tail blackish-brown, tail slightly forked; cheeks and throat dull white with faint dark streaks; underparts dull white, greyer on breast, tinged pale rufous, especially on flanks, undertail-coverts tinged chestnut-brown. Differs from *P. ariel* in blue crown and nape. Sexes alike. Juvenile is duller, browner, with rufous areas paler, pale feather edges. Race *neglecta* resembles nominate but smaller, with less rufous tinge; *timoriensis* differs from previous in having stronger dark streaks on throat. Voice. Song is a high-pitched twittering; contact call "tsweet".
Habitat. Open woodland near water, also human habitations, including towns and cities. Forages over and around trees, and over waterbodies and farmland, especially pasture; has been recorded as feeding over the sea. Roosts in reedbeds and eucalyptus (*Eucalyptus*) trees.
Food and Feeding. Diet includes hymenopterans (including parasitic wasps and ants), hoverflies (Syrphidae) and other dipterans, beetles (Coleoptera), bugs (Hemiptera), Odonata, spiders (Araneae). Forages alone or in small groups, usually higher than 6 m above ground; flight rapid.
Breeding. Generally Jul/Aug-Jan, but mainly Aug-Nov in SW, and opportunistically after rain in arid areas; may often be double-brooded. Solitary or in small groups, usually 2-10 pairs, once 50 pairs in a cave. Nest surprisingly flimsy, a lining of dry grass, leaves (e.g. those of eucalyptus), pine (*Pinus*) needles, sometimes also feathers, placed in hole in tree, cliff, cave, bridge, pier, wall or roof of building, including verandah and ventilator, or in nestbox; artificial sites reported as used more frequently in W; when using crevice, reduces size of entrance by applying mud mixed with plant fibres; will also take over nest of *Hirundo neoxena*, sometimes driving away owners, and build up walls with mud to form small entrance; also reported as entering nests of *P. ariel*; nests reused in successive years. Clutch 3-5 eggs, generally 4; no information on incubation and fledging periods.
Movements. Migratory in SE; mostly resident or partial migrant elsewhere. Forms post-breeding flocks and roosts of hundreds or thousands of individuals. Those breeding in SE Australia and Tasmania migrate to N parts of Australia, islands in Torres Strait and New Guinea, less often to Lesser Sundas, Moluccas and Solomon Is; some reported on breeding grounds in austral winter and a few on non-breeding grounds in summer. Present all year in SW Australia, but passage movements evident in spring and autumn, and fewer reported in winter than in summer. In NE Australia, near Innisfail (Queensland), also present all year below 1000 m, but absent between Dec and Sept on the tableland; population in Atherton region increases in winter months. Vagrants and small flocks of up to 30-35 birds recorded in New Zealand, especially in N South I (Nelson Province and near Farewell Spit).
Status and Conservation. Not globally threatened. Widespread and common breeder in S Australia (few breeding records N of 20° S); locally common on Timor. Density of 0·5 birds/ha recorded in eucalypt forest at Boola Boola. Uses mainly natural nest-sites; habit of exploiting artificial sites is relatively new and may increase, potentially allowing population to expand. Reported to have bred in 1893 in New Zealand (at Oamaru, in SE South I), but this record possibly referable to *Hirundo neoxena*.
Bibliography. Andrew (1992), Barton (1947), Beehler *et al.* (1986), Bell (1979), Blakers *et al.* (1984), Brothers *et al.* (2001), Bull *et al.* (1985), Campbell (1901), Coates (1990), Coates & Bishop (1997), Diamond (1972), Doughty *et al.* (1999), Draffan *et al.* (1983), Falla *et al.* (1981), Filardi *et al.* (1999), Green (1966), Gregory (1995), Griffiths & Holyoak (1993), Hadden (1981), Hastwell (1985a), Heather & Robertson (1997), Henley (1974), Inskipp *et al.* (1996), King (1997), Lord (1956), Macdonald (1988), Mayr (1944), Mayr & Rand (1937), Mellor (1967), Mollison & Green (1962), Morcombe (2000), Morrison & Morrison (1985), Oliver (1955), Pescott (1978), Pizzey & Knight (1997), Rand & Gilliard (1967), Ripley (1964), Robertson, C.J.R. (1985), Robertson, H. & Heather (2001), Saunders & Ingram (1995), Schodde & Mason (1999), Sedgwick (1949), Semmens (1993), Serventy & Whittell (1962), Sharland (1943), Slater *et al.* (1989), Watts (1999), White & Bruce (1986), Wright & Bell (1960).

81. Cliff Swallow

Petrochelidon pyrrhonota

French: Hirondelle à front blanc **German**: Fahlstirnschwalbe **Spanish**: Golondrina Risquera
Other common names: American/North American Cliff Swallow

Taxonomy. *Hirundo pyrrhonota* Vieillot, 1817, Paraguay.
Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Variation clinal, birds becoming smaller and darker from N to S, and races intergrade. Status of race *ganieri* not clear, possibly better merged with nominate. Proposed races *hypopolia* (from Alaska and W Canada S, inland, to EC California, N Utah and NW Wyoming) and *aprophata* (S Oregon) considered to fall within range of variation of nominate; *minima*, described from SW USA (Arizona), considered synonymous with *melanogaster*. Has hybridized with *Hirundo rustica*, and one record with *Tachycineta bicolor*. Four subspecies currently recognized.
Subspecies and Distribution.
P. p. pyrrhonota (Vieillot, 1817) - breeds North America from W & C Alaska and Canada (N Yukon and N Mackenzie E to N Manitoba, N Ontario, S Quebec, Prince Edward I, New Brunswick and Nova Scotia) S to NW Mexico (NW Baja California) in W and, in E, to E USA (S to W Virginia, SE Pennsylvania, W Connecticut and NE Massachusetts, with scattered local populations farther S & E); winters South America.
P. p. tachina Oberholser, 1903 - breeds S USA (SW Utah S to C Arizona, C New Mexico and SW Texas) S to NW Mexico (Baja California); presumed to winter South America.
P. p. melanogaster (Swainson, 1827) - breeds SE Arizona and SW New Mexico S to S Mexico (S to Nayarit and Oaxaca); winters South America.
P. p.ganieri (A. R. Phillips, 1986) - breeds S USA W of Appalachians (WC Tennessee S to S Texas); presumed to winter South America.

Descriptive notes. 13-15 cm; 17-27 g. Nominate race has white to buffy forehead, black lores, glossy deep blue crown, pale grey-brown hindneck; mantle and back glossy deep blue, mantle with whitish streaks, rump light cinnamon-rufous; wings and tail blackish-brown, tail square-ended; head side and throat chestnut, patch of black on throat and uppermost breast; upper breast and sides grey-brown, pale chestnut tinge (variable) on breast, rest of underparts whitish, longer undertail-coverts with dusky grey-brown centres; underwing-coverts grey-brown. Distinguished from most other hirundines by combination of rufous rump and square tail; differs from *P. fulva* in having chestnut throat with black patch, smaller and paler forehead patch. Sexes alike. Juvenile is duller and browner, ear-coverts dark brown, throat and forehead variable in colour and pattern, pale feather margins on upperparts. Races differ in size and coloration, smaller and darker in S: *tachina* is smaller than nominate, forehead cinnamon to light buff; *melanogaster* is same size as last but darker, forehead dark rufous-chestnut, rump darker cinnamon; *ganieri* has darker chestnut undertail-coverts, rest of underparts with only slight chestnut tinge. Voice. Song is a rapid squeaky twittering; other calls include a "chur" call used in many contexts, a plaintive alarm call "purr" and a squeak call used to signal a source of food.
Habitat. Open and semi-open areas, especially near water, including grassland, cultivation, forest clearings and rivers, also human habitations, including towns; prefers open areas for feeding throughout year. Roosts in wetland vegetation. To 2770 m, rarely to 3200 m; recorded to 4000 m on passage. Originally restricted more to W mountainous areas that provided cliffs for nesting.
Food and Feeding. In samples taken throughout North America, diet consisted of 29% Hymenoptera (including ants, bees and wasps), 27% beetles (Coleoptera), 27% bugs (Hemiptera), 14% flies (Diptera), and a few Lepidoptera (mainly moths), grasshoppers and crickets (Orthoptera), dragonflies and damselflies (Odonata), mayflies (Ephemeroptera), lacewings (Neuroptera) and spiders (Araneae); nestling diet in California 39% hymenopterans, 27% hemipterans, 19% beetles, 12% dipterans. In C USA (Nebraska) study, insects from 84 families recorded in nestling diet, with preference for those that swarm, but mainly dipterans (especially of families Dolichopodidae, Simuliidae, Empididae, Chironomidae, Muscidae, Culicidae), hymenopterans (mainly ants and sawflies) and homopteran bugs (mainly aphids and cicadellids). Feeds in flocks of up to 1000 or more birds, in warm weather 50 m or more above ground, lower in cool weather, but often changes height when feeding; frequently makes short glides. Recorded also as feeding on ants on ground. Usually forages within 1·5 km of nest-site, sometimes up to 6 km. Gathers at insect aggregations, uses special call that attracts others to site in bad weather; unsuccessful foragers at colony also follow successful ones to a feeding site; group foraging shown to increase feeding efficiency.
Breeding. Mainly late Apr/May-Jul/early Aug; in USA, first eggs from early Apr in SW (Texas, California) to late May in C & NE (Illinois, Pennsylvania, Massachusetts), and in Jun in Arizona (where breeding coincides with summer rains); single-brooded, two broods recorded rarely in Nebraskan study. Socially monogamous, but extra-pair copulations common. Most colonial hirundine, often in groups of 200-400 pairs, sometimes up to 1000, and colony of 3700 pairs recorded in Nebraska; colony size varies within and among areas, and some pairs solitary. Male

claims and defends breeding site on arrival, little courtship, potential mate gradually accepted at nest-site; copulation inside nest, extra-pair copulations often at mud-gathering sites; male does not guard mate away from nest. Nest-building takes 3-27 days, period shortest when nest wall shared with neighbours; nest retort-shaped, with downward-pointing entrance tunnel, made of mud pellets, lined with dry grass stems; *Hirundo rustica* nest occasionally used as base, and will also evict owners of active nest, e.g. one pair took over that of a Say's Phoebe (*Sayornis saya*) and threw out nestlings; nest sited 1·5-10 m or more above ground or water, attached to cliff, cave entrance, under tree branch (infrequently), bridge (concrete bridges preferred to wooden ones), dam, culvert, or building; often on cliffs and bridges or in culverts in C or SE areas, buildings used more in California and NW & NE USA, and in Nebraskan study colonies on artificial sites larger than those on cliffs; *Riparia riparia* burrows, rock crevices and holes in artificial substrates also used, with mud wall and tunnel added; old nests reused unless containing parasites, and some sites used only in alternate years (occasionally after absence of 2-5 years). Clutch 1-6 eggs, average in various studies 3·3-3·7, declining through laying season; conspecific brood parasitism occurs, at least 22% of nests held parasite eggs in one study and 3·7% in another (parasite has own nest, but also lays in, or transfers egg in bill to, neighbouring nest), and single eggs sometimes destroyed by neighbours (perhaps as prelude to parasitism); male and female share parental duties about equally; incubation intermittent after first 2-3 eggs, continuous from penultimate, period 10-19 days; nestlings brooded continuously for 2-3 days, decreasing to zero at c. 11-12 days, fed with small insects up to days 6-7, then eat adult diet; feeding rates variable, means of 3·4-18·4 per hour in one study, highest in colonies of c. 100 nests, but amount of food per bolus greater in large colonies; nestling period 20-26 days; fledglings fed for further 3-5 days, sometimes longer, young from various colonies form crèche of up to 1000 individuals in trees, on wires or on cliffs, up to 2-3 km from nest, parents locate offspring in crèche by calls, perhaps also by facial markings; juveniles enter other nests and steal food. Mean number of young fledged per nest in various studies 1·56-2·24, and most breeding recruits from clutches of 4 or 5 (varying annually); hatching rate increases with colony size, and fledging success and survival to first year highest for intermediate-sized colonies; main causes of nestling mortality are parasitism by swallow bugs (*Oeciacus vicarius*) leading to decline in fledging success through season, also nest destruction and food shortage as a result of adverse weather, and depredation by House Sparrows (*Passer domesticus*). Recorded longevity 12 years.

Movements. Long-distance migrant, winters in South America. Forms large post-breeding flocks of hundreds, sometimes thousands, of individuals. Leaves breeding grounds Jul-Sept, peak departure in Aug and early Sept; migrates through SE USA, Mexico and Central America into South America, also common passage migrant Aug-Oct in W Venezuela; mixes with other hirundines on migration. Arrives in winter quarters Oct-Dec. Winter range poorly known, apparently extends (mainly E of Andes) from SE Paraguay and SE Brazil S mainly to C Argentina, also rarely Ecuador and Peru, and less numerous and less regular S to Tierra del Fuego; non-breeding ranges of different races uncertain, but nominate recorded in NE Argentina and *melanogaster* in NW Argentina; possibly nomadic in winter. In addition, small numbers recorded farther N, in Panama and California, in winter months. Return N Feb-Apr; arrival in S of breeding range Feb to early Mar, later in N, e.g. mid-Apr in Massachusetts and mid-May in Alaska; *melanogaster* in Arizona returns 6-8 weeks later than other races. More philopatric than other hirundines, and genetically predisposed to return to colony of similar size to natal one: in three studies, 48-74% of birds ringed in year of hatching and recaptured in following year returned to natal site (others mostly to site up to 3·5 km away), and 45-82% of adults returned to same site. Vagrants recorded widely, e.g. in N to NE Asia (Siberia, Wrangel I), Aleutian Is, St Lawrence I, N Alaska, Newfoundland and Greenland, in E Pacific Ocean (Clipperton I, W of Central America), in Caribbean (St Kitts, Barbados), in Falkland Is, and in Europe (British Is, France).

Status and Conservation. Not globally threatened. Total population estimated at c. 89,000,000 birds. Common in much of range; common to fairly common in Mexico. In USA, breeding range has expanded E of Great Plains and in SE in last 50 years as newly constructed buildings, culverts and bridges have provided additional nest-sites; breeding local but increasing, especially in Gulf States, North and South Carolina and Tennessee; first bred in Georgia in 1965, Florida in 1975 and Louisiana in 1980. Also expanded in NE USA from early 1800s as human settlement increased (e.g. first bred New York State in 1817), but disruption of nesting activities in this region by introduced House Sparrows led to a decline and continuing low numbers. House Sparrows also destroyed nearly half of the nests in one year in W Virginia and all 100 nests in a colony in Nebraska. Measures taken to control this species can increase the swallow's numbers locally, e.g. by 87% annually at one site when sparrows were removed. Removal of old nests during winter not only eliminates build-up of parasites, but also reduces number of potential roosting sites for House Sparrows. Will sometimes use artificial plaster nests.

82. Cave Swallow

Petrochelidon fulva

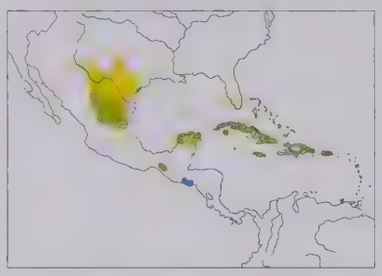
French: Hirondelle à front brun **German**: Höhlenschwalbe **Spanish**: Golondrina Pueblera
Other common names: Cinnamon-throated Swallow (S Mexican and Caribbean races)

Taxonomy. *Hirundo fulva* Vieillot, 1808, Santo Domingo, Dominican Republic.

Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Forms a superspecies with *P. rufocollaris* and often considered conspecific, but recent cytochrome *b* evidence supports treatment as separate species. Race *pallida* recently proposed to represent a distinct species; cytochrome *b* data further suggest, however, that present species consists of two clades, one in W (S USA S to S Mexico) and other in E (Florida and Greater Antilles); additional study required. Several hybrids with *Hirundo rustica* recorded. If genus merged into *Hirundo*, race *pallida* must be named *pelodoma*, as "*Hirundo pallida*" preoccupied. Six subspecies currently recognized.

Subspecies and Distribution.

P. f. pallida Nelson, 1902 - breeds S USA (S New Mexico and Texas) S to NC Mexico (S to S Chihuahua, E Durango, Zacatecas, San Luis Potosí and W Tamaulipas); some migrate to Central America.



P. f. citata Van Tyne, 1938 - S Mexico (C Chiapas, N Yucatán Peninsula).

P. f. cavicola Barbour & A. C. Brooks, 1917 - SE USA (Florida) and Cuba (including I of Pines).

P. f. poeciloma (Gosse, 1847) - Jamaica.

P. f. fulva (Vieillot, 1808) - Hispaniola.

P. f. puertoricensis Garrido *et al.*, 1999 - Puerto Rico.

Descriptive notes. 12 cm; 14-18 g. Nominate race has chestnut forehead to area above eye, blackish lores, glossy blue-black crown, grey-brown hindneck; mantle and back glossy blue-black, mantle streaked whitish, rump light chestnut; wings and tail blackish-brown, tail almost square-ended; head side and throat buffy cinnamon to pale cinnamon-rufous, upper breast and sides similar but with grey-brown tinge, lower breast and abdomen whitish, longer undertail-coverts lightish brown centrally; underwing-coverts pale brownish. Distinguished from *P. pyrrhonota* by darker forehead, paler throat. Sexes alike. Juvenile is duller and browner, variable amount of white on forehead, cinnamon margins on wings and uppertail-coverts. Race *cavicola* closely resembles nominate, but deeper blue crown, wider white streaks on back; *poeciloma* has paler forehead, less white on abdomen, cinnamon more extensive, rustier undertail-coverts; *puertoricensis* has cinnamon or chestnut coloration more intense, also distinctive dark rusty wash on undertail-coverts; *pallida* is larger than others, with light cinnamon throat, collar, forehead and rump; *citata* is small, with paler forehead and rump and more brown on breast and throat than nominate. Voice. Song consists of initial squeaks, a warble and a terminal series of two-tone notes; other calls are a "che", a short "weet" or "cheweet", a series of "che" or "chu" notes and a low-pitched "choo", uttered as alarm calls in predator or territorial contexts.

Habitat. Open areas, often near water, especially ravines and cliffs where caves are present for nesting; also along roads with bridges and culverts, cultivation, and around human habitations, including towns. To 1500 m.

Food and Feeding. Diet includes bugs (both Heteroptera and Homoptera), flies (Diptera), beetles (Coleoptera), wasps, bees and ants (Hymenoptera), butterflies and moths (Lepidoptera), lacewings (Neuroptera), Orthoptera. Stomachs of 36 specimens from Puerto Rico contained at least 22 species, mainly orthopterans; coleopterans found in more than 50% of stomachs, dipterans in 16%, ants in 10%. Most foraging early in day and in late afternoon. Forages at various heights, up to 100 m, in loose flocks, often large ones; mixes with other hirundines and swifts (Apodidae). Flight strong, with frequent periods of gliding. Sometimes feeds along cliff face. Recorded as flushing moths by flying into foliage of tree, then circling back to catch them.

Breeding. Late Feb to early Sept in Texas (probably including early nest-building) and late Apr to early Aug (peak May to mid-Jul) in New Mexico; early Apr to late Jul in Florida; Feb-Oct in Mexico; in West Indies mainly Apr-Aug, from Mar in Cuba, but season in Jamaica unclear (reported as most months except Dec-Feb, and conversely as Oct-May); sometimes two broods in Texas, probably also in Florida. Monogamous, but extra-pair copulations occur. Colonial, in groups of a few tens of pairs, occasionally a few hundreds, and 1500 pairs recorded in one cave; nests sometimes scattered, sometimes clustered, but rarely abutting one another. Nest built by both sexes, either an open flattened half-saucer or half bowl, or enclosed with sides built up to meet an overhang above it, with entrance near apex or (rarely) on side, made of mud pellets, or mud and guano when in cave where bats roost, cup lined with e.g. seed-down, sheep's wool, bark, dry grass and dry algae, feathers added finally, sited usually at least 1 m above ground in cavity or along crack in twilight zone of cave or sinkhole, in cliff, or on bridge, culvert, silo, ruined fort, cathedral or other building (including Mayan ruins on Yucatán Peninsula); nest type varies within and between populations, in NW (race *pallida*) usually open or partially enclosed when in natural site but more often enclosed when in artificial one, elsewhere enclosed nests more common, but in S Mexico (*citata*) open nests also reported; in Cuba often a half-saucer on horizontal surface or in crevice, in Hispaniola often half-cup on wall or, less often, enclosed with side tunnel, in Jamaica often half-cup on vertical or sloping surface, and in Puerto Rico a half-saucer or, less often, enclosed; in Florida, sometimes starts breeding in open nest but adds mud to enclose it during incubation/brood-feeding; one pair used old *P. pyrrhonota* nest; in Texas, species recently found to take over old nests of *Hirundo rustica*, these accounting for 69% of all nests detected for present species during 2001 survey; nests reused within same and successive seasons, last for several years. Clutch usually 3-5 eggs, occasionally 1-2 (perhaps not complete), clutch size decreases during season; incubation probably by both sexes, c. 15-16 days; chicks fed by both sexes, nestling period normally 20-22 days but up to 26 days; fledglings gather in crèches during day, return to nest to roost for a few days. In study in USA (Texas), 78% of eggs hatched, 65% produced fledglings in first brood, 37% in second; second broods more successful in culverts than in caves.

Movements. Migratory in N, resident or partial migrant in S. Often in small groups when not breeding, but flocks of several hundred before migrating. Race *pallida* absent from New Mexico and N Texas in winter months; known to occur in non-breeding season in Central America (El Salvador), but since mid-1980s increasing numbers have overwintered in S Texas and N Mexico. Population in Florida absent in winter, may migrate to West Indies. Mexican and Caribbean populations largely resident, but *cavicola* present in Cuba only locally in late Oct to Jan. Vagrants often recorded farther N in Florida, on E Gulf coast and on Atlantic coast (N as far as Nova Scotia), perhaps reflecting general range expansion; other records include S USA (W & N to California, Arizona, Nebraska), Baja California, Bermuda, Cayman Is, Virgin Is; sight record also from S Canada (Ontario).

Status and Conservation. Not globally threatened. Overall population estimated at c. 8,700,000 birds. Common throughout range. As this species' natural nest-sites are generally widely dispersed, breeding populations often widely scattered; can, however, be locally abundant, e.g. in SW Texas and adjacent S New Mexico c. 5000 individuals at 20 sites in Guadalupe Mts and 2500-3000 at Carlsbad Caverns. Dramatic extension of breeding range to N occurred during past century; first nested in Texas in 1914, New Mexico in 1930 and Florida in 1987; continued N expansion especially marked in Texas and Florida since 1980s; has bred in Arizona (1993). Expansion linked to increased use of road bridges, culverts and other artificial nest-sites, and species has thus benefited from human activity; irrigation and cultivation of arid areas in USA may also have increased the amount of suitable foraging sites; recent survey suggests presence of colonies of *Hirundo rustica* may have facilitated range extension, as present species regularly takes over old nests of latter species.

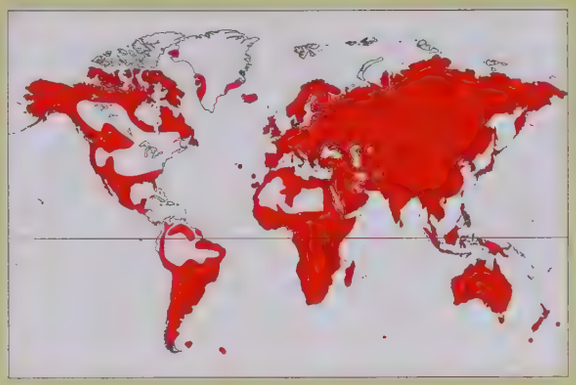
83. Chestnut-collared Swallow

Petrochelidon rufocollaris

French: Hirondelle à bande rousse **Spanish**: Golondrina Cuellirrufa
German: Rotnackenschwalbe
Other common names: Peruvian Swallow; Ecuadorian Swallow (*aequatorialis*)

Taxonomy. *Hirundo rufocollaris* Peale, 1848, near Callao, Lima, Peru.
Genus often merged with *Hirundo*, but DNA studies support retention of separate taxa. Forms a superspecies with *P. fulva*; often regarded as conspecific, but cytochrome *b* evidence supports treatment as separate species. Race *aequatorialis* sometimes referred to by new name *chapmani*, which was proposed in mistaken belief that former name preoccupied. Two subspecies recognized.
Subspecies and Distribution.
P. r. aequatorialis Chapman, 1924 - SW Ecuador (Manabí S to El Oro and W Loja).
P. r. rufocollaris (Peale, 1848) - W Peru (S to Lima).



Descriptive notes. 12 cm; 14-18 g. Nominate race has dark chestnut forehead and hindneck, glossy deep blue crown and back, mantle streaked whitish, and chestnut rump; wings and tail blackish-brown, tail almost square-ended; head side and throat whitish, upper breast and sides chestnut-rufous, lower breast and abdomen whitish, undertail-coverts brown. Sexes alike. Juvenile is duller and browner than adult. Race *aequatorialis* differs from nominate in having cheeks and throat tinged buff, upper breast and sides deeper chestnut. VOICE. A rather gravelly "chrrt" noise is commonly uttered in flight.
Habitat. Cultivation and human habitations, including towns. To c. 1300 m; locally to c. 2000 m in Ecuador.
Food and Feeding. Details of diet not known; aerial insects. Feeds in flocks, often low over ground; mixes with other hirundines. Often forages over water.
Breeding. Jan-Aug. Colonial. Nest enclosed, often with elongated entrance tunnel on side, made of mud pellets, attached to cliff face or under eaves of building. Clutch size and incubation and fledging periods not documented, probably similar to those of *P. fulva*.
Movements. Probably resident; post-breeding dispersal recorded in Ecuador.
Status and Conservation. Not globally threatened. Uncommon to locally common in Ecuador and fairly common in Peru; has limited range. In Ecuador, largest colonies at Celica and Sozoranga (in Loja) and at Portolevo (El Oro), also nests on city buildings in Guayaquil (Guayas); outside breeding season often local, but sometimes in very large flocks (e.g. at roost under bridge over R Daule). Thought to have increased in Ecuador; large numbers now breed in urban sites on Santa Elena Peninsula (W Guayas), where apparently not present in 1950s. Presumed to have benefited from frequent use of houses as nest-sites.

Class AVES

Order PASSERIFORMES

Suborder OSCINES

Family MOTACILLIDAE (PIPITS AND WAGTAILS)

- Small to medium-sized, mostly terrestrial passerines with short neck, long tail, long legs and toes; plumage mostly brown or brownish, often streaked, some species black and white, some with yellow or orange.
- 11·5-24 cm.

- Cosmopolitan, mostly Old World.
- Mostly open habitats, often grassland, a few species in wooded habitats; often near water.
- 6 genera, 65 species, 212 taxa.
- 5 species threatened; none extinct since 1600.

Systematics

The family Motacillidae comprises a group of small insectivorous passerines, the majority of which feed and nest on the ground. Most members of the family are African or Eurasian, with rather few exclusively New World species. The family is currently divided into six genera, comprising a total of 65 species. The genus *Anthus*, by far the largest, contains 43 species of pipit, while *Motacilla* is the next largest, with eleven wagtail species. The longclaws are made up of two species of *Hemimacronyx* and seven of *Macronyx*. The remaining two genera, *Tmetothylacus* and *Dendronanthus*, are both monotypic, represented by, respectively, one pipit and one wagtail.

Of the 65 motacillids currently recognized, as many as 28, including all nine members of the two longclaw genera, breed entirely within the Afrotropics, and one of the *Motacilla* wagtails is confined to Madagascar. One species, the Long-billed Pipit (*Anthus similis*), breeds both in Africa and in southern Asia. Twelve motacillids breed only in Asia, and a further nine have breeding ranges covering both Asia and Europe and, in five cases, extending also to north Africa or extreme north-west America, or to both. The Rock Pipit (*Anthus petrosus*) is the only member of the family restricted as a breeding species to Europe. Two species, both in the genus *Anthus*, are exclusively Australasian in distribution. By comparison with the Old World, America has few pipits and wagtails. Indeed, only a single species, Sprague's Pipit (*Anthus spragueii*), is found solely in North America, while the Buff-bellied Pipit (*Anthus rubescens*) breeds both there and in eastern Asia, and one pipit and two wagtails extend marginally into western Alaska from their Palearctic ranges. Seven pipits occur in the Neotropical Region. Of these, just one extends northwards into Central America and another breeds also in the Falkland Islands. Finally, two interesting pipits are restricted to oceanic islands in the Atlantic. These are Berthelot's Pipit (*Anthus berthelotii*), resident in Madeira and the Canaries in the east Atlantic Ocean, and the South Georgia Pipit (*Anthus antarcticus*), which is found only on the subantarctic island of that name.

Arguments, sometimes quite bitter, have long reigned over the taxonomic status of some geographical forms and of morphologically distinct populations of wagtails, pipits and longclaws. The pipits, in particular, have been the subject of much debate. Recent research, especially that involving DNA, suggests that perhaps nine to twelve current subspecies of *Anthus* and five of *Motacilla* may be better treated as full species. Some of these proposed taxonomic changes may be acceptable according to the criteria of what constitutes a "phylogenetic species", but not necessarily by those defining the concept of a "biological species".

It was previously thought likely, on the basis of the current distribution of members of the Motacillidae, that the family evolved in Africa. More recent analytical studies of mitochondrial and nuclear DNA, especially those by G. Voelker, published in 1999 and 2002, and the work by P. Alström and K. Mild, published in 2003, suggest, however, that the genera *Anthus*, *Dendronanthus* and *Motacilla* have an eastern Asian origin, with

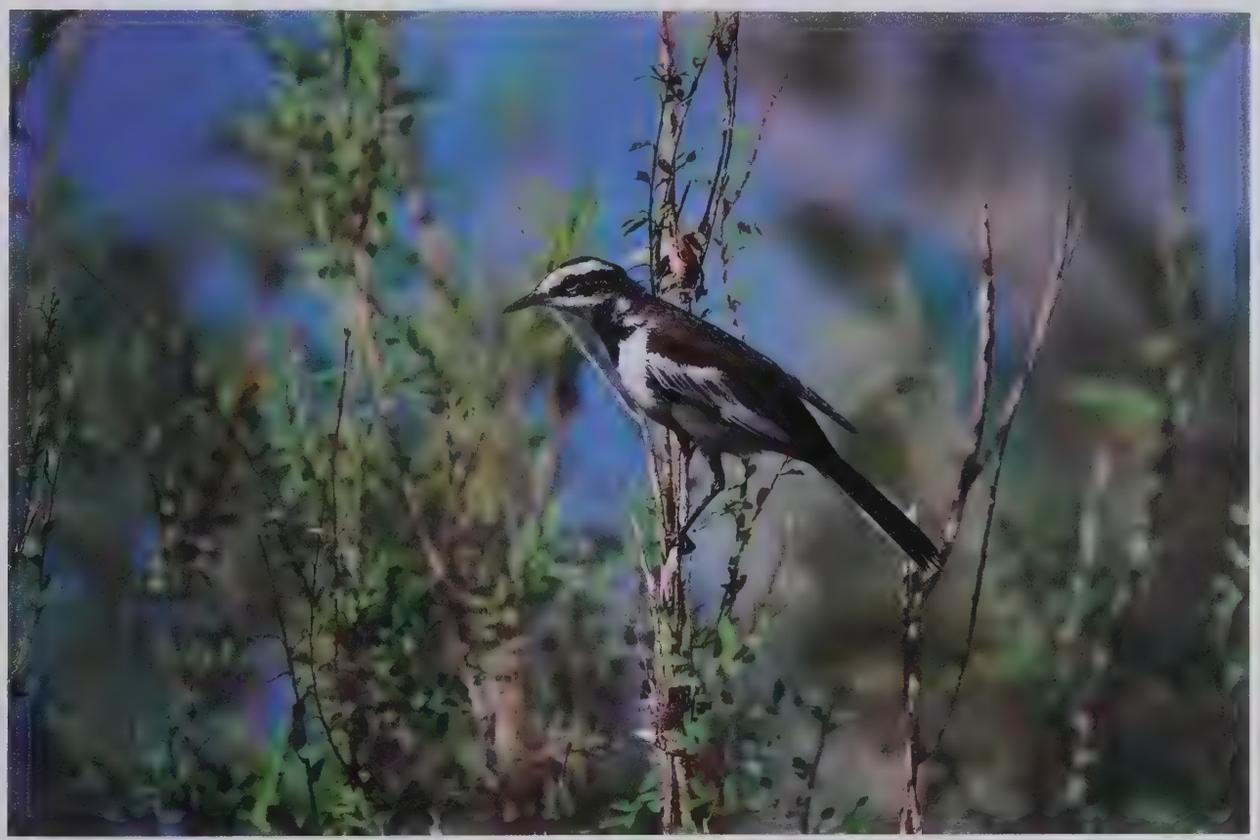
Since the 1980s, there has been considerable interest in non-breeding gatherings of Buffy Pipits (Anthus vaalensis), *Long-billed Pipits* (A. similis) *and Grassveld Pipits* (A. cinnamomeus) *in the region of Kimberley, South Africa. They contained some individuals that defied conclusive identification, until described as two new species: the Kimberley Pipit* (A. pseudosimilis); *and the* ***Long-tailed Pipit****. The first of these is difficult to identify, and somewhat controversial, but the latter is easily picked out by its more horizontal posture and exaggerated tail-wagging; DNA analysis seems to confirm that it deserves separation at the species level, but its breeding grounds remain unknown.*

[*Anthus longicaudatus*, Kimberley, South Africa. Photo: Tom Goossens]

Macronyx, *Heteromacronyx* and *Tmetothylacus* presumably evolving in Africa.

The relationships of Motacillidae have also been open to speculation. At various times in the past, the family has been allied to twelve different passerine families. Work on egg-white proteins suggested affinities with the Old World warblers (Sylviidae) or the Old World flycatchers (Muscicapidae), but chromosomal studies indicated otherwise. In the mid-1980s, the initial DNA studies by C. G. Sibley and J. E. Ahlquist suggested, perhaps rather surprisingly, that Motacillidae should be treated as a subfamily of the weavers (Ploceidae), in which, among others, the Old World sparrows (Passeridae) and the waxbills (Estrildidae) would also be included as subfamilies. Later, these authors concluded that it should be placed between the accentors (Prunellidae) and the sparrows, and suggested that branchings of the passerine lineages occurred within a period of 5 million years.

In 1998, Voelker and S. V. Edwards reported on their molecular-genetic studies of the Motacillidae and possible relatives. In an attempt to determine phylogenetic relationships, they examined a range of wagtails, pipits and longclaws, as well as accentors, Old World sparrows, thrushes (Turdidae), wrens (Troglodytidae) and waxwings (Bombycillidae). Using different models for analysis, they found that all methods supported the contention that Prunellidae and Passeridae were more closely related to Motacillidae than were the other groups that they considered. Passeridae proved to be the closest to Motacillidae in one method, while Prunellidae was closest in another. These authors considered that the inability to determine which of the two families was the more closely related to Motacillidae might also be due to a rapid evolution of all three families.



These recent molecular analyses suggested that, in all methods of phylogenetic reconstruction, the Motacillidae contained three groups. The first comprises the Forest Wagtail (*Dendronanthus indicus*) of Asia, and the second consists of the remaining wagtails in the genus *Motacilla*. The third group is made up of the "true" pipits in the genus *Anthus*, the Golden Pipit (*Tmetothylacus tenellus*), and the longclaws in the Afrotropical genera *Macronyx* and *Hemimacronyx*.

K. H. Voous considered the genera *Motacilla* and *Macronyx* to be more advanced than *Anthus*, which is generally supposed to be the oldest genus in the family. Voelker suggested that *Anthus* arose nearly 7 million years ago in the Miocene, probably in eastern Asia, and that, between 6 million and 5 million years ago, *Anthus* species were present in Africa, the Palearctic and North and South America. Speciation rates were high through the Pliocene period and quite low during the early Pleistocene. He further noted that there had been few intercontinental movements of pipits since 5 million years ago, and that these had been largely restricted to an interchange of birds between Africa and Eurasia. Species "swarms" in North America, Africa and Eurasia, but not in South America or Australia, are the products of multiple invasions, rather than being solely the results of within-continent speciation. Dispersal has therefore, Voelker argued, played an important role in the group's distribution.

As mentioned at the beginning of this section, the genus *Anthus* is the largest in the family. It has representatives throughout the world, with nine species in the motacillid-impoverished New World. Pipits are notoriously difficult to identify in the field, the majority being in general brown or brownish and often streaked. While some world checklists have recognized 34 species of *Anthus*, others list 38 and in some cases 40. Although the current treatment recognizes 43 species, the taxonomy of pipits is still being debated, and new species being described. It is likely that the results of further work on molecular phylogeny will lead to the upgrading of at least nine taxa to the level of full species.

There is still much uncertainty over the specific or subspecific status of many populations of pipits, and much disagreement among taxonomists. For example, controversy exists over the Plain-backed (*Anthus leucophrys*) and Buffy Pipits (*Anthus vaalensis*) of Africa, with various subspecies placed with the former by some authorities and with the latter by others. It is worth remembering that it was not until 1998 that it was generally accepted that the Water Pipit (*Anthus spinoletta*), the Rock Pipit and the Buff-bellied Pipit were three distinct species. Until then, they had generally been regarded as conspecific, representing subspecies of a single species with a distribution extending across the entire Holarctic Region, despite the fact that they show significant differences in habitat preference (see Habitat).

The complexity of the situation is perhaps best illustrated by the taxonomic history of the species known as "*Anthus novaeseelandiae*". Now treated as referring only to a group of nine

The first wagtails of the "black-and-white" group collected in Indochina were misidentified as the race alboides *of the White Wagtail* (Motacilla alba). *This mistake was reiterated in ornithological literature until living birds were studied in the 1990s. It soon became clear that a different species was involved, and that it was one of the most specialized of motacillids, endemic to the lower Mekong and its larger tributaries in Cambodia, southern Laos, and, marginally, Thailand and Vietnam, especially on braided river channels supporting a distinctive mosaic of shrubby islets. The* ***Mekong Wagtail*** *is the only bird endemic to this fragile aquatic system, which is coming under increasing threat from a suite of development projects.*

[*Motacilla samveasnae*, Kampi pool, Kratie, Cambodia. Photo: Pete Davidson]

The name Anthus novaeseelandiae *once referred to an extremely variable species that ranged from South Africa through Asia all the way to New Zealand. It has now been split into four so that nine races (including the nominate) become the Australasian Pipit; resident South-east Asian forms become the Paddyfield Pipit* (A. rufulus)*; African races become the Grassveld Pipit* (A. cinnomomeus)*; and migratory Asian birds become* ***Richard's Pipit****. At first, all these taxa were assumed to form a superspecies, but recent DNA studies suggest that they are not very closely related. Moreover, further subdivisions at the species level are highly likely.*

[*Anthus richardi*, Sohar, Oman. Photo: Hanne & Jens Eriksen]

Australasian subspecies, it was previously considered to include numerous other races that occur over a vast range extending from the Afrotropics, western Siberia and the Russian Far East through southern Asia and Australasia to several oceanic archipelagos. In 1986, however, this large complex of taxa was split into several species, based on geographically isolated populations or groups of subspecies. Thus, Richard's Pipit (*Anthus richardi*), comprising only the migratory Asian populations, the Paddyfield Pipit (*Anthus rufulus*), containing the sedentary races of southern and South-east Asia, and the Grassveld Pipit (*Anthus cinnamomeus*), representing the African races, are now recognized by most authors as full species, together forming a superspecies with the Australasian Pipit (*Anthus novaeseelandiae*). In addition, the populations breeding in New Guinea and Australia are regarded by many ornithologists as constituting a further species, distinct from that found in New Zealand and on the island groups to the south and east.

Moreover, much heated discussion has centred on the further separation from the Grassveld Pipit of some mountain forms. The population that breeds on the high plateaux of Lesotho is now accepted by most authorities as a separate species, the Mountain Pipit (*Anthus hoeschi*), because it has different calls and displays from those of the local race *rufuloides* of the Grassveld Pipit, and the two show segregated breeding where they occur together. Jackson's Pipit (*Anthus latistriatus*), thought to breed in montane grasslands bordering the Rift Valley, is distinctive not only in its very dark plumage coloration but also in its vocalizations; nevertheless, it is regarded by many as simply a dark morph of the Grassveld Pipit. In addition, the population found in the highlands of south-east Nigeria and west Cameroon is thought by some to represent a further species, although its treatment as such is strongly disputed by other taxonomists.

There seems to be less disagreement with regard to the taxonomic status of the Woodland Pipit (*Anthus nyassae*). This species was formerly treated as a subspecies of the Long-billed Pipit, and the two are, indeed, very similar in appearance and have similar songs. They differ significantly, however, in ecology: the Woodland Pipit frequents miombo woodland in Zambia and adjacent countries, whereas the Long-billed Pipit favours boulder-strewn hillsides with sparse bush or tree cover through southern and eastern Africa.

Two new African species have come to light in recent years, both detected among wintering pipits on grassland around Kimberley, in South Africa. These are the Long-tailed Pipit (*Anthus longicaudatus*), first described as a separate species in 1996, and the Kimberley Pipit (*Anthus pseudosimilis*), described as recently as 2002. Furthermore, it is believed that an undescribed *Anthus* taxon, very similar to the Long-billed Pipit, in Kenya may represent either a new species or, perhaps more likely, an undetected race of the Woodland Pipit. If it proves to be the latter, then this would represent a considerable extension of that species' range.

Despite, or perhaps because of, the lack of agreement on species, subspecies and relationships, no attempts had been made to hypothesize the phylogenetic relationships among all of the species of *Anthus*. Recently, however, various morphological characters have been used in an effort to classify the pipits. These included plumage colour and pattern, shape and length of the hind claw, tail pattern, wing formula and overall body size. In 1999, Voelker published information on his investigation of the nucleotide sequencing of the mitochondrial cytochrome *b* gene, a study aimed at determining relationships among 41 supposed species of pipit. From his molecular studies and his hypothetical phylogenetic tree, Voelker argued that few of the morphological characters used by earlier taxonomists were truly useful in demonstrating relationships, and that some were, in fact, misleading. For example, some taxonomists believed that species with yellow axillaries, namely the Rosy (*Anthus roseatus*), Striped (*Anthus lineiventris*) and Yellow-tufted Pipits (*Anthus crenatus*), or those with green wing edges, the Rosy and Olive-backed Pipits (*Anthus hodgsoni*), were closely related to each other, but this was not borne out by his molecular studies and his resulting hypothetical phylogenetic tree.

Voelker's analyses of DNA sequences supported four major groups, or clades, within the genus. The first clade comprises the three small-bodied African species, the Sokoke Pipit (*Anthus sokokensis*), the Bush Pipit (*Anthus caffer*) and the Short-tailed Pipit (*Anthus brachyurus*), a grouping that had previously been recognized by several authors on the basis of the morphological characters of body size, wing formula and hind-claw shape. B. P. Hall and R. E. Moreau thought that the Sokoke and Bush Pipits were most closely related, but this was not borne out by Voelker's hypothesis. The second is a largely Palearctic clade. It includes

These photographs show rather different-looking birds, but each of them is a ***Yellow Wagtail****. They are just three of the many subspecies which, despite marked differences in plumage, are genetically almost identical. Interbreeding freely at overlap zones, and producing fertile hybrids, they defy separation under the biological species concept. Nevertheless, certain forms retain consistent differences in plumage and voice on either side of a narrow zone of intergradation, suggesting that their status very closely approaches that of viable species. Thus, the Yellow Wagtail complex is a systematic conundrum, which many decades of research have failed to decipher. One recent analysis suggests that it may justify being split up into three species-groups:* taivana*;* flava*; and* tschutschensis*. Another analysis linked* taivana, tschutschensis *and* macronyx *as one group, and the Western Palearctic forms as another species. Further molecular work concluded that the entire complex was paraphyletic, in other words that all its constituent forms shared a common ancestor, but not all descendants of the ancestor were included in the grouping. These sets of results are somewhat contradictory, underlining that they rely to some extent on subjective interpretation and the vagaries of laboratory technique. Clearly, a great deal more research is required before a stable taxonomy gains widespread acceptance, and until that time the Yellow Wagtail, in its innumerable manifestations, is best retained intact.*

the Buff-bellied, Meadow (*Anthus pratensis*), Rock, Water, Rosy, Red-throated (*Anthus cervinus*), Pechora (*Anthus gustavi*), Olive-backed and Tree Pipits (*Anthus trivialis*). The third clade is an American one that consists of the Correndera (*Anthus correndera*), South Georgia, Paramo (*Anthus bogotensis*), Hellmayr's (*Anthus hellmayri*), Sprague's, Yellowish (*Anthus lutescens*) and Short-billed Pipits (*Anthus furcatus*). The Correndera and South Georgia Pipits were found to be sister-taxa, as Hall contended in 1961, but these species did not form a superspecies with the old "*A. novaeseelandiae* complex". The molecular phylogeny supported a sister relationship between the Yellowish Pipit and Sprague's Pipit, rather than, as Hall suggested, between Sprague's and Short-billed Pipits. The fourth and largest clade is African, Eurasian and Australasian, and comprises 18 species. Within this last group, Voelker's phylogenetic tree did not show a close relationship among the species previously included within *A. novaeseelandiae*, except that Richard's and Paddyfield Pipits were apparently sister-species. Both the African and the Australasian taxa were more closely related to other species, the African ones to the Long-billed Pipit, and the Australian and New Zealand ones to the Woodland Pipit. Moreover, molecular studies of New Zealand taxa suggested that some populations on small islands near New Zealand warranted species status.

The analyses by Voelker further suggested that a number of geographically separated races were not, in fact, closely related to the species in which they were placed. For example, the subspecies *brasilianus* of Hellmayr's Pipit and the subspecies *catamarcae* of the Correndera Pipit are geographically remote from other populations of those species, and probably merit full species status. In addition, Voelker found the newly recognized Long-tailed Pipit to be closely related to the Buffy Pipit, and that a population of the Long-billed Pipit was sufficiently distinct to be separated as a new species, the Kimberley Pipit.

Evidence from the "molecular clock", which theoretically predicts that molecular change is constant throughout time and space, suggests that speciation came about through the following dispersal events. Africa was invaded by *Anthus* from South-east Asia and Mongolia twice, about 6·5 million years ago and, again, more than 3·5 million years ago. About 2 million years later the Australasian Pipit arrived in its present area, having moved across Arabia and southern Asia from Africa, where it had a common ancestry with the Woodland Pipit. Present-day Neotropical forms arrived through North America, where the ancestral form(s) became extinct, about 6 million years ago. Sprague's Pipit resulted from a divergence from the South American Yellowish Pipit, which subsequently reinvaded North America. The South Georgia Pipit reached its present home from South America about 1·5 million years ago. Later, there was a dispersal from north-east Asia into Alaska; a further movement through that route, as well as dispersals from north-east Africa to west Asia, from south-east Europe to north Africa and from west Europe to Greenland, took place much more recently. The molecular clock further suggests that the separation of the Correndera and South Georgia Pipits, of Hellmayr's and the Paramo Pipit, and of the Afrotropical Long-billed and Malindi Pipits (*Anthus melindae*) occurred over a period of about 1-2 million years.

These results support the contention that dispersal, rather than the range-splitting effects of climatic or geological barriers, was a major factor in the speciation processes in the genus *Anthus*. This is because the time scale would appear to be too short for major climatic events, or geological ones such as plate tectonics, to have been an important influence.

The taxonomy of the pipits is clearly in a state of flux. Molecular studies are a relatively new technique and will continue to develop, but already they have shed much light on the likely affinities of species. These studies, however, need to be supported by, and interpreted together with, other information, including that derived from behavioural and ecological studies.

Following the pipits, three other motacillid genera form an all-African group of ten species. Seven species of longclaw make up the genus *Macronyx*. Sharpe's Longclaw (*Hemimacronyx sharpei*) of Kenya was formerly classified in this genus, but is now generally placed in the genus *Hemimacronyx*, along with the Yellow-breasted Pipit (*Hemimacronyx chloris*) of South Africa, which was previously included in *Anthus*. A few taxonomists do not recognize the genus *Hemimacronyx* and prefer to retain these two species in their former respective genera. The recent molecular studies, however, provided evidence to support an earlier assertion that the Yellow-breasted Pipit is not a true pipit. Voelker and Edwards thought it reasonable, therefore, to place it, together with Sharpe's Longclaw, in *Hemimacronyx*. Their molecular work also indicated that all pipits and longclaws with yellow underparts, namely the Golden Pipit in the monotypic

*The **Australasian Pipit** currently comprises nine subspecies, several of which are isolated geographically. This photograph shows the race* chathamensis, *which is endemic to the remote Chatham Islands in the South Pacific. It is said to differ from nominate birds in its buffier underparts, although this individual looks predominantly white below, with a broad pale supercilium and fine markings on the chest. This form, and several others in the* Anthus novaeseelandiae *complex, may warrant treatment as separate species. A full review of morphological, behavioural and genetic data is required.*

[*Anthus novaeseelandiae chathamensis*, Chatham Island, New Zealand. Photo: Robin Bush/ Oxford Scientific Films]

The pipits are sexually monomorphic, essentially terrestrial, and relatively homogeneous in terms of behaviour and morphology. With its dull plumage and slender bill the ***Grassveld Pipit*** *is a typical example. Like all its congeners, the upperpart plumage is drab brown and slightly mottled, to provide camouflage against soil and stones; the underparts are pale, with darker speckling on the chest. As an adaptation to its terrestrial lifestyle, the legs, toes and claws are long and strong. This feature is common to all motacillids, allowing them to run at high speeds and to adopt a tall upright posture when scanning for prey or predators. Another family characteristic clearly shown in this photograph is the great length of the tertial feathers: in contrast to the situation in most passerines, they cloak the primaries almost entirely. This feature probably serves to protect the flight-feathers from the constant glare and sunlight which falls on open-country birds and eventually causes their plumage to fade and become brittle.*

[*Anthus cinnamomeus rufuloides*, Midmar Nature Reserve, KwaZulu-Natal, South Africa. Photo: HPH Photography/ Photo Access]

*This **Cape Longclaw** shows off the origin of the name "longclaw". As in some pipits, and a range of other ground-dwelling birds, the hind claw in* Macronyx *is curved and elongated, presumably as an adaptation to a terrestrial lifestyle. In terms of general appearance, the longclaws are not unlike the pipits but they differ in being sexually dimorphic and relatively robust, a little more lark-like, with much brighter underparts. There are seven species in total, all of which have pink, yellow or orange on the throat or belly, and six of which have a black breastband, echoing a pattern commonly found in wagtails* (Motacilla).

[*Macronyx capensis colletti*, Wakkerstroom, eastern South Africa. Photo: Johannes Ferdinand]

Tmetothylacus and all species of *Hemimacronyx* and *Macronyx*, appear to be close relatives.

Turning to the wagtails, the Forest Wagtail of Asia is placed in a monotypic genus, *Dendronanthus*, rather than with the *Motacilla* wagtails. Molecular studies did not produce any convincing evidence with regard to its relationships with the other motacillids. The Forest Wagtail resembles *Motacilla* in general plumage, but behavioural and morphological studies, as well as egg colour, suggest that it may be closer to *Anthus*. For example, it looks and acts more like a pipit when on the ground and, as some *Anthus* species, it spends much time in trees; the latter trait, however, is also exhibited to some degree by the Grey (*Motacilla cinerea*) and Mountain Wagtails (*Motacilla clara*). Perhaps importantly, it is associated with woodland, and not closely with water. Voelker and Edwards, therefore, considered that *Dendronanthus* should be placed closer to *Anthus* than to *Motacilla*, as suggested by one of their trees of motacillid relationships.

The genus *Motacilla* includes eleven species of wagtail, the most recently described of which, the Mekong Wagtail (*Motacilla samveasnae*) from southern Indochina, was first named in 2001. *Motacilla* is an Old World group, breeding mainly in the Palearctic and Oriental Regions. Three species are Afrotropical, and one other is confined to Madagascar. Two members of the genus have extended their ranges to the New World, where the Yellow Wagtail (*Motacilla flava*) and the White Wagtail (*Motacilla alba*) both breed on the tundra in Alaska, thereafter migrating to eastern Asia; the White Wagtail breeds also in south-east Greenland.

Voelker suggested that *Motacilla* arose in the eastern Palearctic 4·5 million years ago, and within a short time colonized Africa, where the prevailing climate had resulted in extensive areas of grassland in the north-east. A re-expansion of forests isolated the first colonists, and a subsequent shift back to grassland allowed a second colonization of this continent to take place about 2·9 million years ago. Although he believed that the early flooding of the Mediterranean and of the Red Sea might have presented a barrier to ancestral intercontinental movements by *Anthus*, these and similar events appear not to have been an important factor for *Motacilla*. In more recent times, the White Wagtail has colonized north Africa and North America, reaching the latter via both Alaska and Greenland, and the Yellow Wagtail has colonized North America from the eastern Palearctic and north Africa from the west Palearctic. Similarly, the Grey Wagtail has reached north Africa and some Atlantic islands.

According to the results of this research, environmental changes caused by climatic shifts would have led to the Afrotropical species diverging from the Eurasian ones. In Eurasia itself, it seems likely that glacial activity was an important factor in motacillid speciation events, particularly in the region of the Ural Mountains and the Yenisey River, resulting in the separation of western Palearctic forms from eastern ones.

Previously, the general consensus has been that *Motacilla* consisted of three superspecies. These are the "yellow group", the "stream group" and the "pied group". The first contains the Yellow, Citrine (*Motacilla citreola*), Cape (*Motacilla capensis*) and Madagascar Wagtails (*Motacilla flaviventris*), and the second comprises the Grey Wagtail and the Mountain Wagtail. The third, the "pied group", consists of the White Wagtail, the White-browed Wagtail (*Motacilla maderaspatensis*), the Japanese Wagtail (*Motacilla grandis*) and the African Pied Wagtail (*Motacilla aguimp*). The recently described Mekong Wagtail would belong to the last group. The validity of these groupings, however, is not borne out by recent studies involving analyses of mitochondrial DNA, which indicate that none of the three supposed superspecies is monophyletic.

In the 1930s, some taxonomists argued that the Madagascar and Mountain Wagtails were conspecific with the Grey Wagtail. C. E. Vaurie refuted this, maintaining that the three were morphologically quite distinct, but he considered that the White Wagtail and the African Pied Wagtail were conspecific, a view doubted by others. J. M. Winterbottom believed that the Cape Wagtail was close to the original form from which the Palearctic wagtails diverged, and that the "White Wagtail group" evolved from this ancestral form by suppression of yellow coloration and intensification of black. The "Yellow Wagtail group" had, he argued, evolved by the processes of a shortening of the tail and an increase in the amount of yellow, and the "Grey Wagtail group" by a lengthening of the tail and an increase in the yellow in some cases. Other taxonomists, such as M. P. S. Irwin, believed that the Cape Wagtail was allied to the Yellow and Citrine Wagtails.

Recent molecular-genetic studies, by Voelker and by A. Pavlova and colleagues, indicate that the Mountain and Cape Wagtails are sister-taxa, forming a sister-group to the Madagascar

As a rule, the "true" wagtails are much more boldly patterned than pipits and longclaws. One of their most characteristic traits is behavioural, giving rise to their English name: they wag their tails almost incessantly, especially after alighting on a new perch. In addition, their tails are very long, with distinct white edges to the outer rectrix. Unlike most pipits, the wagtails have blackish legs. The genus Motacilla *falls quite neatly into three informal styles, the "black-and-white", the "yellow" and the "riverine" groups. The* ***African Pied Wagtail*** *is clearly a member of the first group. According to some molecular analyses, but not others, it forms part of the White Wagtail* (M. alba) *superspecies.*

[*Motacilla aguimp vidua*, KwaZulu-Natal, South Africa. Photo: Jurgen & Christine Sohns/FLPA]

Wagtail, which, in turn, is a sister-taxon to all other *Motacilla* wagtails studied. Controversially, and significantly, the Yellow and Citrine Wagtails as currently constituted were both found to be paraphyletic. The west Palearctic race *werae* of the Citrine Wagtail and the Mongolian and east Asian race *taivana* of the Yellow Wagtail are grouped separately from the east Palearctic form of the former and the north-east Asian race *tschutschensis* of the latter. The implication is that the Citrine Wagtail should be split into two species, as *M. citreola* and *M. werae*, and the Yellow Wagtail into three species, as *M. flava*, *M. taivana* and *M. tschutschensis*. The Grey Wagtail then becomes a sister-taxon to all of those except *M. flava*, and this larger group is then a sister to the White and White-browed Wagtails, with the African Pied Wagtail becoming a sister-taxon to all of these. The newly constituted *M. flava*, restricted to the western Palearctic and central Asian races, and being a sister-taxon to the group containing all

The ***Forest Wagtail*** *is a fascinating bird of unknown ancestry. It is patterned more like a wagtail, behaves more like a pipit, and is more arboreal than either. Its pale supercilium, prominent wingbars and double breastband give the impression of a wagtail, but its horizontal posture, pink legs and habit of perching in trees suggests that it should perhaps be placed closer to* Anthus *than to* Motacilla, *a contention supported by some molecular studies. To date, however, such studies have failed to offer any convincing insight regarding its affinities, so it remains in its own monotypic genus. Interestingly, it does not wag its tail up and down, but from side to side in a strange exaggerated motion.*

[*Dendronanthus indicus*, Wajima, west central Honshu, Japan. Photo: Hirozo Maki]

*The **Golden Pipit** is another distinctive species occupying a monotypic genus. The male has brilliant yellow underparts and a black breastband, thus indicating a closer relationship with the* Hemimacronyx *and* Macronyx *longclaws than with the* Anthus *pipits. It occurs in overgrown shrubby grassland of a kind shunned by most other motacillids, where it often perches on top of bushes, as shown here. This photograph also clearly reveals the Golden Pipit's most unusual feature: it is the only passerine with the lower portion of the tibia unfeathered. No functional explanation has been forwarded for this peculiarity, nor do we know why it should be so rare.*

[*Tmetothylacus tenellus*, Buffalo Springs National Reserve, Kenya. Photo: Martin B. Withers/ FLPA]

of the aforementioned taxa, is thus separated considerably from the other forms with which it has traditionally been considered conspecific. Finally, the group containing the Mountain, Cape and Madagascar Wagtails, which form a clade, separated from all other wagtails within 100,000 years from the time when the genus first colonized Africa.

Alström and A. Ödeen reached similar conclusions on the evidence obtained from their analyses of mitochondrial DNA. When looking at nuclear DNA, however, they found evidence indicating that the "White Wagtail superspecies" was a sister-taxon to the Citrine Wagtail *sensu lato*. This clade appeared to be a sister to one group of Yellow Wagtail subspecies, namely the nominate race and *iberiae*, *cinereocapilla*, *pygmaea* and *thunbergi*. The other Yellow Wagtail clade, consisting of the races *tschutschensis*, *macronyx* and *taivana*, becomes a sister to the Grey Wagtail, which in turn is sister to the Cape, Mountain and

*Juvenile pipits are much like their parents, but young wagtails are relatively duller than theirs. Compared with adults they have less well-defined head and underpart patterns, tending towards buffy or greyish where adults might be black; this juvenile **White Wagtail** is a perfect example. Young birds also tend to have a small orange flange at the gape. The identification of juvenile wagtails is slightly more complex than that of adults, in some cases because the species lack yellow pigmentation when young. Thus the adult Citrine Wagtail* (Motacilla citreola) *is mostly stunning yellow, but the juvenile is an anonymous-looking mixture of grey, black and white.*

[*Motacilla alba alba*, Navarre, Spain. Photo: José Luis Gómez de Francisco]

Madagascar Wagtails. Thus, whereas the Citrine Wagtail remains intact, the Yellow Wagtail appears as two quite separate species, but the "Cape Wagtail group" seems robust and its treatment as such is supported by all studies.

Plumage characters, with additional evidence from vocalizations, support trees based on nuclear DNA work more strongly than they do those based on mitochondrial DNA. Studies by Y. A. Red'kin and V. G. Babenko found that hind-claw structure and the plumage characters of juvenile, first-winter and adult female individuals supported the contention that *taivana* and *macronyx* are sister-taxa, and that these, together with *tschutschensis*, *simillima* and *plexa*, form a group separated from all other Yellow Wagtail races. Ödeen suggested that *thunbergi* and *macronyx* are probably convergent, that *taivana* may be distantly related to the western group of subspecies, and that *simillima* and *macronyx* belong to the western group but resemble *taivana* as a result of introgression of *taivana* genes or those of an extinct close relative.

A further example of the difficulties and uncertainties surrounding the relationships of the *Motacilla* wagtails concerns the African Pied Wagtail. The results of nuclear DNA studies indicate that this species forms part of the *M. alba* superspecies, whereas analyses of mitochondrial DNA contradict this. Alström and Ödeen suggest that the lack of congruence between trees based on different areas of evidence is due to convergence, old introgression, different rates of evolution of characters, and random sorting of ancestral variants of mitochondrial DNA.

Irrespective of molecular-genetic findings, a number of wagtail subspecies have, over the years, been treated as distinct species by various authors. These opinions have been based largely on differences in voice, plumage and structural characters. Not surprisingly, several of the well-marked races of the Yellow Wagtail, especially *lutea*, *feldegg* and *taivana*, have sometimes been considered to be separate species. Equally, some authorities recognize the distinctive eastern black-backed subspecies *lugens* of the White Wagtail as a full species, known as the "Black-backed Wagtail", and the same treatment is afforded by some authors to other White Wagtail races, such as *personata*, the "Masked Wagtail". Similarly, the north-western race *simplicissima* of the Cape Wagtail is sometimes treated as a full species. In contrast, Alström and Mild, in their 2003 monograph, regarded some widely recognized subspecies as being indistinguishable in terms of plumage. In the case of the Yellow Wagtail, for example, they synonymized *angarensis* and *simillima* with *tschutschensis* and merged *melaneogrisea* with *feldegg* and *plexa* with *thunbergi*, and they found *werae* to be inseparable from the nominate race of the Citrine Wagtail and *dukhunensis* inseparable from the nominate race of the White Wagtail.

Quite clearly, a great deal of additional research is required, both in the field and in the laboratory, before the relationships of the genera, species and subspecies in the family Motacillidae, and the true status of some of the taxa, are understood. It should be borne in mind that much of the recent work involving DNA analyses is, in some respects, rather speculative, and the conclusions drawn are to some extent subjective and open to individual interpretation. Although there seems little doubt that at least some of the findings of investigative research of this nature will ultimately prove to be accurate, and the decisions based on such work sustainable, studies involving DNA are still in their infancy. Moreover, many more years of work on molecular genetics are desirable before the implications of the findings thus derived are understood with sufficient confidence. For the present, it is considered more appropriate, therefore, to adopt a more traditional approach to the classification of the Motacillidae, especially at the species and subspecies level.

Morphological Aspects

All members of this family have certain striking similarities. They are all small to medium-sized, short-necked, slender, elongated, long-tailed insectivorous passerines, and they all possess long, often pale or flesh-coloured legs, toes and hind claws. The sexes are similar in size. The hind toe of most species is elongated, and in the case of some longclaws can reach 4 cm in length.

Differences in tail length and in the shape and length of the hind claw are useful in the separation of motacillid species, especially the pipits. Ground-dwellers have a long, slightly curved hind claw, whereas that of arboreal species is generally shorter and more curved. The wing has nine long primaries, and a much-reduced tenth; the tertials are generally long. The outer feathers of the long tail are variably edged white or buff. All motacillids

At least 70% of motacillids prefer to live in grassland or other open-country vegetation. The ***Meadow Pipit****, for example, breeds in natural habitats such as tundra, moorland, meadowland, heathland, bog and saltmarsh. Because of its predilection for open habitats this species was pre-adapted for survival in man-modified environments such as fallow arable land and rough pasture. This tolerance of agricultural landscapes makes it one of Europe's commonest birds.*

[*Anthus pratensis pratensis*, Clwyd, Wales. Photo: Mike McKavett/ Windrush]

*The **Correndera Pipit** occurs in South American grassland, especially in moist pastures. In the lowlands of Argentina it abounds in the* pampas *region, where it is the commonest pipit. It also occurs further south, in Patagonia, but here it occupies taller and wetter grassland because it is otherwise outnumbered and outcompeted by the Short-billed Pipit* (Anthus furcatus). *Another population is Andean, ranging through the mountains of north Argentina, Bolivia and south Peru, where it inhabits* puna *grassland, arid plains, pastures, bogs and lakeshores.*

[*Anthus correndera correndera*,

have a bill that is long, pointed, notched and often slender, with a nasal operculum and rictal bristles.

Although the *Macronyx* longclaws are considerably larger than the pipits and wagtails, there is otherwise rather little size variation within the family. The smallest species include the Short-tailed Pipit of Africa, with a body length of only 11·5-12·5 cm and a wing length of just 65-70 mm, while the Bush Pipit of southern Africa and the Yellowish and Chaco Pipits (*Anthus chacoensis*) of South America are only slightly larger. Other pipits and wagtails commonly have a wing length of 80-100 mm, an overall length of 16-21 cm and a mass of 15-31 g, although Striped Pipits are heavier, weighing 30-38 g. Most *Macronyx* longclaws usually have wings exceeding 100 mm in length, and the largest species, such as the Cape (*Macronyx capensis*) and Fülleborn's Longclaws (*Macronyx fuellebornii*), weigh 46-64 g.

The sexes of most species overlap extensively in size, although the largest and heaviest individuals are usually males. In the genus *Anthus*, the two sexes are very similar in plumage. In the case of the Golden Pipit, the longclaws and the wagtails, on the other hand, the male is usually the more brightly coloured, especially in the breeding season. In addition, the male Grey

*Unlike the case of larks (Alaudidae), no pipit is a desert specialist, although a few species will straggle into barren terrain. This **Grassveld Pipit** is seen on the baked sandy soil of the Kalahari Desert, but we can be sure that grassland or tussocky plains are to be found nearby. In the Namib, not far to the north, the dry grassland gives way to endless sandy dunes, where pipits are absent and only larks survive. Part of the reason for their failure to invade truly arid environments is dietary: larks can dig for plant material and subsist on windblown seeds, while pipits are more reliant on live insects, a scarce resource wherever vegetation is lacking.*

[*Anthus cinnamomeus bocagei*,
Kalahari Gemsbok
National Park,
South Africa.
Photo: Terry Carew/
Photo Access]

Several species of pipit are restricted to montane environments. The ***New Guinea Pipit*** *falls into this bracket, usually living between 3200 m and 4500 m, though occasionally down to 2500 m, in the highlands of New Guinea, where it is the only pipit in evidence. It frequents open areas above the tree-line, especially where short grass and carpets of alpine vegetation are found. To survive at these altitudes it has to consume larger quantities of seeds and other plant material than do pipits of lower elevations, probably in part because the supply of insect food is barely sufficient.*

[*Anthus gutturalis gutturalis*, Mt Scratchley, south-east New Guinea. Photo: William S. Peckover]

Wagtail has a black throat in the breeding season, a feature only very rarely exhibited by the female.

The *Anthus* pipits are generally drab, brown birds with variable amounts of darker streaking on the back and breast. They have a worldwide distribution, and in habits and coloration they resemble larks (Alaudidae). Unlike the latter, however, they have a tarsus that is angled at the back (acutiplantar), has unbroken sheaths at the sides and has fused scales or scutes at the front, whereas the alaudid tarsus is flat at the back (latiplantar) and has the sides covered with scales. A few members of the genus, notably the Red-throated and Rosy Pipits when in breeding plumage, are more colourful. More subtle colour in the plumage is shown by the Olive-backed Pipit, which has olive-green upperparts, by both the Rosy Pipit and the Striped Pipit, which have greenish edges of the wing feathers, and by the Yellow-tufted Pipit, with its yellow axillaries. Further, two Neotropical species, the Yellowish and Ochre-breasted Pipits (*Anthus nattereri*), have the underparts suffused with yellow.

Far more striking in appearance is the Golden Pipit of north-east Africa, the male having golden-yellow underparts with a black breastband, a golden-yellow band across the wings, and a yellow rump and tail sides. The yellow underparts and black breastband make it appear similar to a small longclaw. The female and young birds, when at rest, more closely resemble true pipits, but in flight they display yellow on both the upper and the lower wing surfaces and the tail edges.

The seven species of *Macronyx* longclaw are robust, often lark-like birds. Having streaked brown upperparts, they are not unlike the pipits in general appearance, but they all have brightly coloured yellow, orange or pink underparts. Six of the species have, in adult male plumage, a black necklace or breastband reminiscent of the black or dark bands on the upper breast of the African Pied, Cape and Mountain Wagtails and of the Golden Pipit. Grimwood's Longclaw (*Macronyx grimwoodi*) lacks this breastband. Longclaws show a strong resemblance to American meadowlarks (*Sturnella*) in appearance, habitat and behaviour. As long ago as 1946, H. Friedmann drew attention to these ecological counterparts. The two *Hemimacronyx* species, the Yellow-breasted Pipit of South Africa and Sharpe's Longclaw of Kenya, have yellow underparts in breeding plumage.

Although the Asian Forest Wagtail, with its brown upperparts, also resembles a pipit when on the ground, it has a marked white supercilium, prominent white wingbars and two black breastbands, making it quite unlike any *Anthus* species. This striking plumage may suggest that it is closer to the *Motacilla* wagtails, but molecular-genetic studies indicate that it is probably more closely related to the pipits (see Systematics). It is largely arboreal, and it wags its tail from side to side, rather than up and down.

Adults of the "true" wagtails, in the genus *Motacilla*, are generally more strikingly marked or more brightly coloured than are the pipits. Instead of being brown and streaked, the wagtails either exhibit a combination of grey, black and white or have some yellow in the plumage. Young wagtails are much duller, and some of the "yellow" species, notably the Yellow Wagtail, are rather pipit-like, both in appearance and in habits. All of the wagtails, however, have a noticeably long tail with white outer feathers, and they characteristically wag the tail up and down. On the basis of general morphological characteristics, the ten species of *Motacilla* fall into three main groups: a "black-and-white group", a "yellow group", and a "riverine group". A further species, in Madagascar, does not fit easily into any one of these main cat-

*The **Upland Pipit** is another poorly known bird of the montane zone, usually found between 1200 m and 3000 m in the Himalayas and south China, though it spends the non-breeding season at slightly lower altitudes. An unusual population occurs in the highest hills of Hong Kong, where this photograph was taken, and where the species breeds between 500 m and 1000 m. In all cases, it prefers steep, boulder-strewn slopes with scattered bushes and grassy patches. Appreciable in this photo are its rather stout bill, and also its habit of perching like a sentinel on prominent rocks and other suitable vantage points.*

egories. The first group consists of the Japanese Wagtail, the White-browed Wagtail of India and Nepal, the African Pied Wagtail and the Mekong Wagtail, as well as the various subspecies of the White Wagtail of Eurasia. All of these have predominantly black-and-white plumage, and the tail is similar in length to the wings. The yellow group comprises two Eurasian species, the Yellow and Citrine Wagtails, and the Cape Wagtail of eastern and southern Africa. These three are characterized by having the tail shorter than the wings and by displaying much yellow in the plumage. The two riverine species, the Grey Wagtail and the Mountain Wagtail, have the tail longer than the wings; both occur on fast-flowing, rocky, wooded streams, the first in Eurasia and the second in the African uplands. The Madagascar Wagtail somewhat resembles members of the yellow group, but it also has several plumage features that are reminiscent of the two riverine species.

Members of the family sometimes exhibit aberrant plumage as a result of melanism, albinism or partial albinism. Partial albinism has been noted in an African Pied Wagtail and a Grassveld Pipit. There are 17 records of Japanese Wagtails possessing aberrant plumage, and all were considered to be partial albinos. The possibility that they were hybrids between Japanese and White Wagtails, or partially melanistic White Wagtails, was thought unlikely in view of their calls and songs and their relationships with other individuals. Melanism has also been reported in an African Pied Wagtail. Soil staining, which causes local vari-

*In summer the **Rosy Pipit** breeds high in the Himalayas and associated mountain ranges from Afghanistan to Myanmar and southern China, perhaps ascending higher than any other motacillid. It has been recorded up to 5300 m above sea-level, but breeds a little lower on alpine meadows and grassy slopes, especially where snow-melt has created boggy ground. Severe conditions grip the Himalayas in winter, and the Rosy Pipit is forced to escape by descending in altitude; it reaches a lower limit of 1500 m and appears in submontane habitats such as agricultural land.*

[*Anthus roseatus*,
Shey, Ladakh, India.
Photo: Otto Pfister]

*Despite their close taxonomic alliance, the **Rock Pipit** and the **Water Pipit** occupy very different ecological niches. The Rock Pipit is a bird of open rocky seashores and estuaries; it is almost always encountered at coastal sites, and it spends most of its time within the intertidal zone. A few individuals ascend to 400 m on hills slightly inland, and others breed on rocky islands in inland lakes. The Water Pipit, in turn, breeds at much higher altitudes, usually around streams or damp grassy areas between 650 m and 3200 m, and never at sea-level. The Rock Pipit is a partial migrant, but it always favours coastal sites, while the Water Pipit provides an interesting example of a seasonal switch in habitat selection. In winter it descends to the lowlands, frequenting freshwater habitats such as rice fields, coastal lagoons and waterlogged grassland. Some birds from Central European populations travel north to Britain, where they overwinter on watercress beds, and in other suitable habitats. Given these distinct and inflexible differences in habitat requirements and migratory patterns, it now seems remarkable that this complex was previously thought to contain no more than a single species, and even more surprising that this view held sway until 1998.*

[Above: *Anthus petrosus littoralis*, Helsinki, Finland. Photo: Markus Varesvuo.

Below: *Anthus spinoletta coutellii*, Sohar, Oman. Photo: Hanne & Jens Eriksen]

ations in plumage colour, is known to affect Berthelot's Pipit and may be a widespread phenomenon.

Notwithstanding what has been stated in the preceding paragraphs, plumage differences between wagtails and pipits are not always clear-cut, this being notably so in the case of immatures and females. Some pipits bear a strong resemblance to wagtails. For example, the Buffy Pipit of southern Africa shows a distinct lack of streaks in its plumage. As its English name indicates, it is a buff-coloured bird and it could be mistaken for an immature wagtail as it forages on grassland, wagging its tail in typical wagtail fashion. So, too, might the pale, slim Tawny Pipit (*Anthus campestris*), which breeds in much of Europe and across to Tibet and winters in Africa just south of the Sahara. It is generally unstreaked, with white outer tail feathers, it has a wagtail-like build, it carries its body in a horizontal posture, as does a wagtail, and it also pumps its tail down and up. A Tawny Pipit, especially when observed at long range, could quite easily be taken for a juvenile Yellow Wagtail, although the latter, unlike the pipit, has black legs and usually some black markings on the breast. The very close relationship between the wagtails and the pipits is also evident from the remarkable similarity in the songs and parachuting courtship displays given by, for example, the Tree Pipit and the Grey Wagtail (see Breeding).

For those motacillids for which details are available, adults generally have two moults annually, one before breeding, which is normally incomplete, and one after breeding. Some species, among them the White-browed Wagtail and Berthelot's Pipit, as well as some Rock Pipits, do not undergo a pre-breeding moult. In some migratory species, the post-breeding moult is completed before the departure to winter quarters, but in others it may be completed during stopovers en route, or after arrival on the wintering grounds. Many species begin the partial pre-breeding moult while still in the wintering area, continuing the moult when they are back on the breeding grounds. Juveniles generally undergo a partial moult, involving the feathers of the head and body and some of the wing-coverts, within a month or two of leaving the nest, followed by another partial moult in the late winter and early spring. Thereafter they resemble the adults very closely. In some cases, the first juvenile moult is suppressed, particularly among individuals that have hatched late in the season, as has been recorded for White Wagtails in the Netherlands.

Habitat

Members of this family have radiated out into most available habitats. They occur from the coast and offshore islands, on cliffs and rocks and along the seashore, where the Rock Pipit and the South Georgia Pipit are found, to the tops of high mountains, where the Water Pipit and the Mountain Pipit breed. They range also from the northern tundra, the breeding habitat of the Buff-bellied, Pechora and Red-throated Pipits, to grassland in the subtropics and tropics, the home of the Yellow-breasted, Buffy and Plain-backed Pipits and some of the South American pipits. Northern conifer forests harbour Olive-backed Pipits, and in broadleaf forests there are Forest Wagtails in Asia and Sokoke Pipits in East Africa. In the Afrotropics, rocky hillsides with scattered trees support Striped and Long-billed Pipits, and above 1000 m rocky hills and *kopjes* hold Yellow-tufted Pipits. In open woodland in that continent there are Bush and Woodland Pipits, as well as wintering Tree Pipits, and by rivers, lakes, marshes and other wetlands in the Old World species such as the White-browed, Mekong, African Pied, Yellow and Cape Wagtails are found. Forested mountain streams are inhabited by two specialists, the Grey Wagtail in Eurasia and the Mountain Wagtail in Africa.

Some motacillids exploit suburban developments and urban habitats. White and Japanese Wagtails, for instance, often frequent human settlements and built-up areas, and they and other species flock into towns and cities at dusk to roost on buildings or trees (see General Habits). Parks and gardens often provide ideal foraging habitats for some members of the family. The Cape Wagtail, for example, is one of the most widespread garden birds in southern Africa, where it sometimes becomes tame (see Food and Feeding). Industrial landscapes, such as open-cast coal mines, support a few species, including Meadow and Tawny Pipits.

Despite the wide variety of habitats used by members of the family, at least 70% of all motacillids have a distinct preference for grassland or other open-country environments, such as dunes, heathland and moorland, and both fallow and arable land. All the longclaws and many of the pipits occur on grassland, whether wet or dry and with or without bushes and scattered trees. Grasslands at sea-level support such diverse species as the Malindi Pipit, the South Georgia Pipit and the Pangani Longclaw

The race brasilianus *of* ***Hellmayr's Pipit*** *is a common inhabitant of lowland grassland in Brazil, Uruguay and Argentina. It seems to favour relatively tall grass, as well as rank pastures and agricultural land. In the Andes, the nominate race is usually found in a rather different setting: it thrives in the short-sward grassland of the* puna *zone, and on rocky and shrubby mountainsides with patches of stunted turf. The lowland and Andean forms may, in fact, not be closely related. They are geographically isolated, and the results of recent molecular analysis suggest that a significant genetic gap exists between them.*

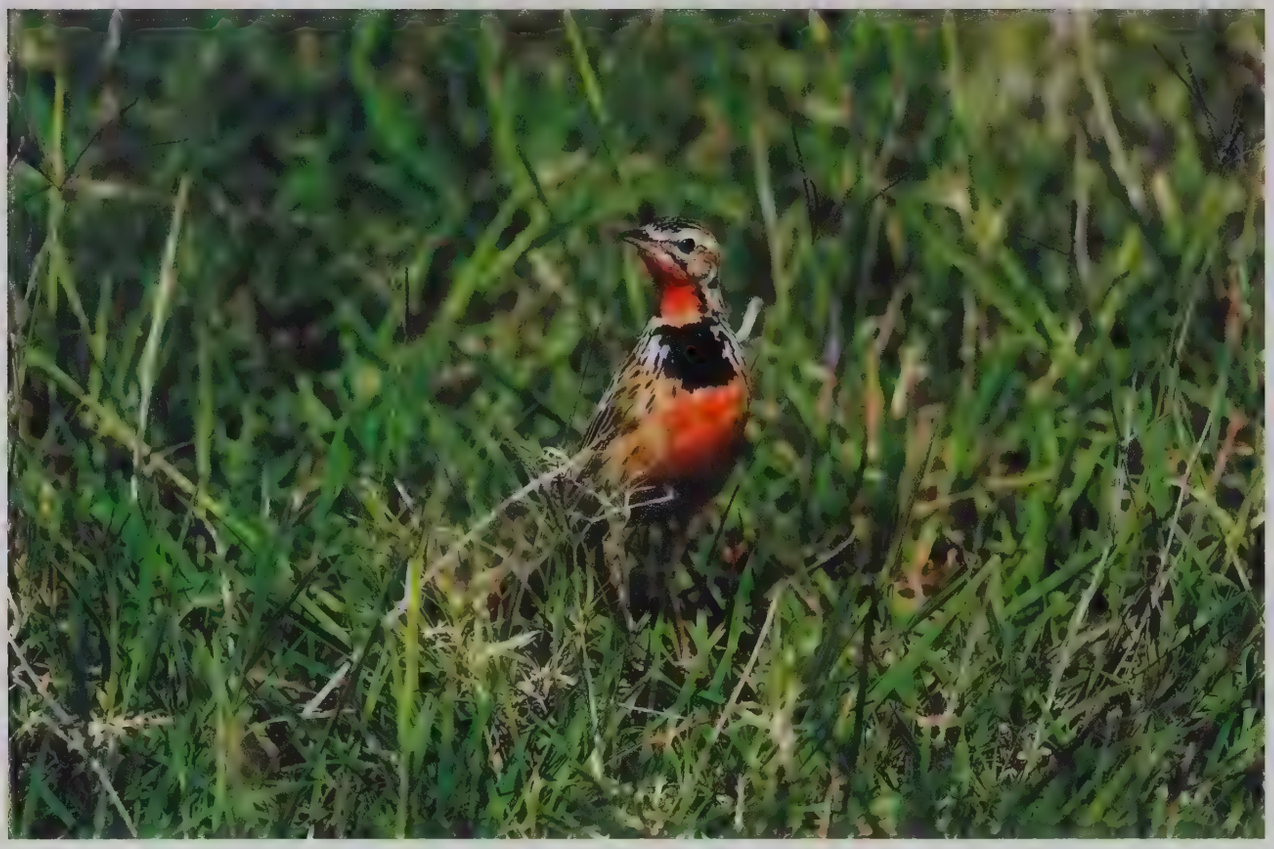
[*Anthus hellmayri brasilianus*, Serra da Canastra, Minas Gerais, Brazil. Photo: Edson Endrigo]

A few pipits are almost inextricably associated with trees. The ***Olive-backed Pipit*** *tends to breed at the edge of taiga woodland, and forests of oak, birch, alder and pine. For the winter, it migrates south to tropical climes, where it lives in plantations of mango, cardamum and coffee, and visits various types of semi-open country, as long as trees are available. When disturbed, this species habitually escapes upwards to the safety of a high branch, giving a diagnostic fizzing call-note as it goes. As might be expected, the hind claw of this arboreal pipit is distinctly shorter and more curved than that of its terrestrial relatives.*

[*Anthus hodgsoni*, China. Photo: Göran Ekström]

(*Macronyx aurantiigula*). Montane grassland in Africa is the haunt of the Yellow-breasted Pipit and Sharpe's Longclaw, while the avifauna of the *puna* grasslands of the Andes includes the Short-billed, Correndera and Paramo Pipits. The temperate grasslands of Europe and North America are inhabited by, respectively, the Meadow Pipit and Sprague's Pipit, the ecological counterparts of which in Asia, Australia and New Zealand are Richard's and Paddyfield Pipits and the Australasian Pipit. In South America, the Yellowish, Ochre-breasted, Hellmayr's and Correndera Pipits all occur on grassland, pastures and fields. Some species, such as the Correndera Pipit, tolerate a wide range of altitudes, whereas others are more restricted, at least in the breeding season, to certain altitudinal limits.

Dry, open fields are utilized by many species, especially when on migration. In southern Africa, for example, fallow and arable land is a favoured haunt of Grassveld and Buffy Pipits. Meadow Pipits will nest in such habitats in Europe, and Yellow Wagtails breed in cereal crops and in fields with potatoes and other root crops, albeit at lower densities than they do in their preferred habitat of floodplain grassland. Dry, short grassland is preferred by some *Anthus* species, such as the Buffy and Sprague's Pipits, and moister, taller grassland by others, of which the Red-throated Pipit is an example. On its breeding grounds in southern Canada, Sprague's Pipit shuns non-native vegetation, such as is found in seeded pasture, hayland or cropland, and is almost restricted to native grassland with dead vegetation less than 10 cm high. Non-native pasture has taller vegetation and an increased amount of bare ground, which probably makes it less attractive to this species. Many motacillids avoid more bushy parts of grassland, but grassland with scattered bushes or developing scrub is frequented by species such as the Cape Longclaw and the Golden Pipit in Africa. These birds use the bushes as vantage points or songposts. Even in montane pastures, Water Pipits often employ a tree, bush or rock outcrop as a lookout post.



Motacilla wagtails generally prefer wetter grassland than that frequented by pipits. They regularly breed in the floodplains of lowland rivers or along the edges of lakes, streams and rivers, as is typical of the Cape, Yellow and Madagascar Wagtails and the majority of the "black-and-white group" (see Morphological Aspects). Several of the longclaws, notably Fülleborn's and Rosy-breasted Longclaws (*Macronyx ameliae*), also rely on wet or damp grassland, a habitat utilized similarly by Plain-backed Pipits. Willow (*Salix*) mires, sedge (Cyperaceae) marshes and peat bogs attract Red-throated Pipits, and are also common breeding sites for Yellow and Citrine Wagtails in the northern parts of their ranges.

The most specialized of all *Motacilla* species in terms of breeding habitat is the Mekong Wagtail. This recently described species occurs in north-east Cambodia and adjacent parts of Thailand, Laos and Vietnam, where it breeds during the latter part of the low-flow season on the Mekong River and a small numbers of its tributaries. Most records of this species are from rivers more than 100 m wide, and all localities where it has been found are below 100 m in altitude. The Mekong Wagtail requires braided sections of river with swift-flowing water, and with a distinctive mosaic of sandbars and gravel shoals and numerous emergent rocks and bushes, a habitat sometimes referred to as "channel mosaic". Here, it has frequently been observed to forage within the tops of bushes projecting above the water surface. Significantly, it appears to shun exposed areas, such as sandbars and earth banks, as well as higher islands with vegetation resembling that of the adjacent floodplain. Although the wagtail may use exposed areas during the non-breeding season, when water levels are much higher, there are very few records of it for this period of the year.

Forest Wagtails, as already mentioned, are found in broadleaf forests. They breed in a wide variety of such forests, both deciduous and evergreen, and occasionally even in pine (*Pinus*) woodland. This Asian species is migratory, spending the non-breeding season mostly in the south-east of that continent. It is then found in the same types of habitat, but also at the edges of humid forest and in plantations and parkland, and it occasionally roosts in mangroves and reedbeds. Reedbeds are also a common roost-site of Yellow Wagtails during the post-breeding migration.

During the non-breeding season, irrigated areas, especially rice fields, are favoured by a number of motacillids, including Yellow, Citrine, White and Japanese Wagtails, as well as the river-breeding Grey Wagtail. Similarly, farmyards and manure heaps attract various pipits and wagtails, primarily outside the breeding season, as also do sewage pools and settling beds. All of these places, of course, provide a rich source of insect food.

An interesting example of a change in habitat between the breeding and non-breeding periods is provided by the Water Pipit

The genus Macronyx *is endemic to Africa, and wherever its constituent species are found in sympatry they tend to be segregated by habitat. In Kenya, where this photograph was taken, the* ***Rosy-breasted Longclaw*** *is fond of tussocky grassland, preferably in seasonally or permanently flooded areas, and often near swamps, marshes, rivers, lakes, coastal lagoons and other wetlands. This attraction to damp meadows and rushy bogs minimizes overlap and competition with the Yellow-throated Longclaw* (M. croceus), *a species which tends to occupy drier ground, and even bushy areas where grass is thicker and longer.*

[*Macronyx ameliae wintoni*,

in Europe. During the summer, this species nests on alpine slopes and upland plains, generally between 1000 m and 3000 m, in areas with short grass and boulders, and usually near streams or wet patches. After nesting, it moves down into the lowlands and seeks out freshwater areas, including, in particular, flooded meadows and dried-out fish ponds. Some of the central European population migrates north-westwards to Britain, where watercress beds, which depend on a steady flow of pure fresh water, are a likely place for the observer to find this pipit.

Although several species of motacillid may utilize the same habitat, there is usually some partitioning on a finer scale. For example, Water Pipits and Meadow Pipits overlap on mountain pastures in west and central Europe, but Water Pipits favour short grass for foraging, whereas Meadow Pipits forage in longer vegetation. In areas where Citrine and Yellow Wagtails occur together, the former forages in wetter habitats, even wading in water. Similarly, where Richard's Pipit co-occurs with the Tawny Pipit, it prefers more fertile and moister grasslands than its congener, even feeding in marshy meadows alongside Yellow Wagtails. The same partitioning of the habitat can be seen in South America. Short-billed and Correndera Pipits are found together in grassland habitats in the Andes, but the former occurs in more arid country, whereas the Correndera Pipit exploits lusher areas with taller grass. Likewise, the Yellowish Pipit breeds on damp lowlands in Brazil, whereas Hellmayr's Pipit is found on adjacent drier hillsides; these ecological preferences, however, are not obvious outside the breeding season.

Similar examples are evident in Africa, where two or three species of longclaw may live alongside each other, as in parts of Zimbabwe. In such cases, they are usually segregated by finer habitat choices. The Rosy-breasted Longclaw tends to feed in the centre of low-lying areas of wet grassland, or vleis, and the Cape Longclaw on drier, shorter, sparser grassland, whereas the Yellow-throated Longclaw (*Macronyx croceus*) prefers areas where trees and bushes intrude and the grass is thicker and longer. In addition, Yellow-throated Longclaws will use some habitats, such as montane grassland, only in areas where Cape Longclaws are absent. The various subspecies of the Yellow Wagtail also differ slightly in habitat preferences in their wintering areas. Thus, the south-west Asian race *feldegg* often spends the non-breeding season along rivers in Africa, whereas the central European nominate race and the one breeding immediately east of it, *lutea*, prefer grassland in their African winter quarters.

General Habits

Most members of the family are terrestrial, both foraging and nesting on the ground. They take to the air only when flushed or during song and courtship displays, and, of course, when dispersing or on migration. Some species crouch or hide when disturbed, flying only if danger is imminent. Relatively few habitually perch in trees. Among the *Motacilla* wagtails, both the Grey and the Mountain Wagtails, when disturbed, readily fly up to trees along the upland rivers which they frequent. They also use branches as perches from which to launch aerial flycatching sallies out over the river, and they perform display-flights from trees. The aberrant Golden Pipit also frequently perches in trees and bushes, as do Cape Longclaws and Yellow-breasted Pipits, Olive-backed and Tree Pipits, and Woodland, Long-billed, Bush and Striped Pipits. They all fly to trees when disturbed, in addition to which they may sometimes forage in trees, even walking along branches, or use trees as perches during courtship displays. In Africa, termitaria are used by longclaws as vantage points or songposts. The more terrestrial Grassveld, Buffy and Plain-backed Pipits occasionally perch in low trees or bushes in the Afrotropical grasslands, but they usually prefer a termite (Isoptera) mound or a rock as a perch.

A major exception to this general picture is the Forest Wagtail of eastern Asia. Although this species does regularly forage on leaf-covered ground, it is equally likely to seek food in trees. Moreover, it is the only member of the family that habitually nests in trees, sometimes well above the ground, making it a truly arboreal species. Other motacillids are known to build nests in bushes and trees (see Breeding), but none of them does so on a regular basis throughout its range.

Tail-wagging is a characteristic trait of many members of the family. It is, of course, a common, conspicuous and well-known aspect of the behaviour of the wagtails, and the word *Motacilla* itself could be rendered in English as "tail-mover", but many pipits also exhibit tail-wagging when feeding or during displays. Whereas all wagtails of the genus *Motacilla* wag the long tail up

and down, the Forest Wagtail sways the tail and the hind part of the body from side to side in a distinctive, exaggerated motion, normally while perched among the branches of a tree. Despite some early statements that this species, when disturbed, flies up to an overhanging branch, where it sits while wagging its tail slowly up and down and pivoting the hind end from side to side, subsequent observations indicate that the tail is always moved laterally, together with the rear body.

The way in which a pipit moves its tail, and the posture adopted at the time, can be a helpful or important clue to its identification. Some species, such as the Plain-backed and Buffy Pipits, stand very upright, whereas others, among them the Long-tailed Pipit, have a more horizontal stance. Some wag the tail up and down continuously for several minutes at a time, while others raise the hind body and then, slowly and deliberately, depress both it and the tail several times. As an example of these differences in tail-wagging behaviour, the Upland Pipit (*Anthus sylvanus*) flicks its tail quite sharply, in contrast to the Olive-backed Pipit, which gently moves its tail up and down. Generally, the majority of pipits wag the tail rather slowly. The Buff-bellied Pipit bobs its tail up and down or swings it from side to side, nodding its head at the same time. When a Grassveld Pipit is disturbed, it runs, holding the body horizontal, and then pauses, standing erect, before running and pausing again; at each pause, it dips its tail one to three times, but it does not perform the pronounced tail-wagging of, for example, the Tawny Pipit or the Buff-bellied Pipit. The Plain-backed Pipit also gives exaggerated wags of the tail during pauses between walking or running, and the Buffy Pipit, pausing in very upright posture, wags its tail very deliberately as it raises and then lowers the hind part of its body. In contrast, the recently described Long-tailed Pipit moves its tail in the manner of a *Motacilla* wagtail, while adopting a horizontal posture, being rather similar to the Tawny Pipit in this respect. As a final example, Golden Pipits, too, while perched in trees or bushes, wag the tail in typical *Motacilla* fashion.

Although tail-wagging is a widespread trait among the Motacillidae, its function is unclear, and the reasons why wagtails, pipits and some other avian species perform this action may be varied. It has often been suggested that tail-wagging or other body movements made by birds living by fast-flowing water may perhaps render the birds less conspicuous. Tail movements by wagtails and pipits may also serve as signals, for example, to other flock-members, and so help to maintain the unity of foraging flocks. Exaggerated tail-wagging is used as a signal during courtship and other displays, and may serve an important territorial function. Another hypothesis is that tail-wagging is a signal to predators. When a wagtail or pipit lands on the ground, it usually wags its tail immediately. This movement supposedly then attracts any nearby predator, drawing it out of cover while the bird is still alert and able to avoid capture. If no predator is spotted, the motacillid begins to feed; it wags its tail at intervals, in case a predator has arrived nearby. A further hypothesis is that the action may have the effect of disturbing insects. If this is so, tail-wagging could be expected to increase when the bird is foraging in shade, in order to compensate for the poorer visibility caused by reduction in contrasts between dark and light colours. Indeed, this is what happens in the case of an unrelated Australian species, a fantail known as the Willie-wagtail (*Rhipidura leucophrys*); observations demonstrated that individuals of this species, when foraging in the shade, wagged the tail at more than twice the rate of those foraging in the sun. Yet another possibility is suggested by observations of a coastal motacillid in north-west Europe. Rock Pipits, when foraging along the shore, wag the tail seemingly as an intention movement, as when they are about to lunge at a fly.

Some motacillids are resident or make only short-distance movements after breeding. This is particularly so in the case of the two species confined to Atlantic islands, the South Georgia and Berthelot's Pipits, but some others, such as the Afrotropical longclaws and Yellow-breasted Pipit, are also sedentary. All of these species occur in pairs or in small family groups. Many members of the family, however, are partially or entirely migratory, and these often gather into flocks, sometimes large ones, outside the breeding season. They also congregate to roost when on migration or in the non-breeding quarters. At these times, thousands or even tens of thousands of wagtails may assemble at dusk. In Nigeria, for example, 20,000-50,000 Yellow Wagtails were recorded at a winter roost. Other species, including White, Citrine, African Pied, Cape and Forest Wagtails, likewise roost together in large numbers. Grey Wagtail roosts, on the other hand, tend to be small, consisting of fewer than 50 individuals, but larger ones

*Not only does the **Yellow-throated Longclaw** prefer dry grassland away from water, but it is also attracted to recently burnt areas. Shortly after a blaze swept through, this young bird arrived to harvest easy pickings. With the sward burnt down, items such as charred insects and seeds become readily visible, where once they were well concealed, and a variety of open-country birds converge to take advantage of the feast.*

[*Macronyx croceus croceus*, Masai Mara National Park, Kenya. Photo: Morten Strange]

Although some pipits or longclaws are often seen around the margins of grassy wetlands, none have such aquatic lifestyles as the wagtails. The most famous riverine species are the Grey Wagtail (Motacilla cinerea) *of Eurasia and the Mountain Wagtail* (M. clara) *of the African highlands, but many species, perhaps a majority, have a tendency to use river-edge or wetland-edge habitats at least some of the time. The* ***Japanese Wagtail****, for example, is most often found at riversides and lakesides, or near ponds, aquaculture and rice fields. However, this beautiful species, virtually endemic to Japan, is by no means as tied to fresh water as first impressions might suggest. It happily feeds in parkland and pastures far from water, and it frequents the hinterland of sea coasts in winter. The* ***Madagascar Wagtail*** *adopts a similar lifestyle. It spends most of its time in open areas near water, be it fresh, brackish or salty. It is the only motacillid in Madagascar, however, and its niche is relatively broad, allowing it to feed around settlements and in a variety of cleared areas away from water. Wagtails that habitually feed on streams tend to have longer tails than non-aquatic wagtails. It seems likely that the long tail is an adaptation for maintaining balance on rocks, especially when darting the head out for insects: wagtails with shorter tails tend to overbalance when they attempt this technique! Long tails are also related to aerial foraging as they improve manoeuvrability.*

*The **Citrine Wagtail** is very closely tied to the edge of wetlands in some portions of its range. In Nepal, for example, this species conspicuously adopts the waterside niche while the closely related Yellow Wagtail* (Motacilla flava) *lives in drier and grassier environments. In all regions, Citrine Wagtails often forage around wetlands, picking insect prey from the water's surface, or darting out over the water to snatch flying insects. They are also regularly seen walking on mats of floating vegetation or even wading in shallow water.*

[*Motacilla citreola*, India. Photo: Gertrud & Helmut Denzau]

are occasionally formed, as shown by reports of hundreds roosting under a bridge in west Europe and up to 200 roosting in Poland, while up to 100 were counted at a roost on the Yemen coast in January. All these wagtail species have much in common in their roosting behaviour and choice of roost-sites.

Different species of wagtail frequently roost together. In Asia, for instance, mixed roosts containing Forest, Yellow, Citrine and White Wagtails occur. Sometimes, pipits and other passerines may join the wagtails. In central England, ten Water Pipits and 13 Meadow Pipits were observed at a White Wagtail roost which was also attended by Reed Buntings (*Emberiza schoeniclus*). Red-throated Pipits, which often associate on wet ground with Yellow Wagtails, will also roost communally with them. A particularly interesting observation was made in western Poland, where an August roost on the floodplain of the River Oder contained, at times, over 2000 Yellow Wagtails, nearly 2800 Eurasian Linnets (*Carduelis cannabina*), 200 Grey Wagtails, five Meadow Pipits and a wide range of other species, including Blue Tits (*Parus caeruleus*), Eurasian Goldfinches (*Carduelis carduelis*) and Reed Buntings.

Grey Wagtails frequently spend the night with other members of the family. In the UK, during the winter months, small numbers have been found in White Wagtail roosts at several sites, including a sand quarry. In this region, the White Wagtails, which numbered 125 to 340 individuals, are of the local British and Irish subspecies *yarrellii*, commonly known as the "Pied Wagtail". Elsewhere, the large coastal Grey Wagtail roost in North Yemen, mentioned a couple of paragraphs above, was associated with a gathering of 225-300 White Wagtails. Similarly, Grey Wagtails in India also assembled at sunset to join other wagtail species for roosting. During the winter of 1942/43, in the Lebanese capital of Beirut, some 20-25 Grey Wagtails arrived each night with sparrows (*Passer*), although the two species roosted separately.

Researchers in the UK found that, during the winter months, most *yarrellii* White Wagtails attending a roost in Berkshire foraged by day in areas within 12 km of the roosting site. There was some interchange of individuals between roost-sites within 10 km of each other. In a study of a Yellow Wagtail roost on the Jos Plateau, in Nigeria, individuals that had been caught and colour-marked at the roost were observed over 13 km away from it during the day, but some flew in to the roost in the evening from sites 32 km away. The catchment area for another very large roost of Yellow Wagtails in Nigeria was estimated to be 270 km^2 in November, increasing to 825 km^2 in February. In Germany, Grey Wagtails were found to spend the day within 2-3 km of their roosting sites.

Pre-roost gatherings and aerial displays are a commonly recorded characteristic of White Wagtails. At the well-studied Berkshire roost, just mentioned, such gatherings took place in the open, where the wagtails could readily be seen from the air. The birds started to collect together in their feeding areas an hour or more before sunset, when they preened and fed sporadically, and made short flights; when they left and headed off towards the roost-site, they made characteristic calls. They then gathered in an area near the roosting site, where they stood about, frequently preening, for up to an hour. These pre-roost gathering areas are used from year to year, and are more constant in location than is the roost itself. Similar events have been observed in many other parts of this species' range. Near a roost-site in Switzerland, for example, White Wagtails used the flat roof of a shopping centre as a pre-roost gathering area, before flying to different roosts in trees, mainly conifers. In Egypt, wintering White Wagtails headed towards the roost in small flocks and collected on open ground, before flying to roost in sugar cane (*Saccharum officinarum*). They would circle around and over the roost, calling, before dropping like stones into the tall cane, at first in ones and twos and then in larger numbers. The overhead circling followed by the sudden dive into the roost perhaps serves to confuse aerial predators, which often attend large roosts of this and various other avian species.

Similar pre-roost gathering sites appear not to be a regular feature for other wagtail species. In southern Africa, Cape Wagtails fly in to the roost at dusk in ones and twos or in small groups of ten or so, approaching from all directions; they circle overhead and call, before diving, directly or on a zigzagging path, down into the reeds or trees. Small groups do sometimes collect up into larger parties of 25 or more individuals at nearby sites, and they then fly in to the roost together. Separate flocks of 20 or more Yellow Wagtails have also been observed to come in just before dusk, circling around and dropping down into dense vegetation to roost; late arrivals dropped straight in, without circling.

*The **White Wagtail** uses an enormous variety of habitats, both natural and man-made, and it is found across a vast geographical range. Although it often occurs alongside water, it is liable to be encountered in almost any category of grassland and open country. Its great mobility and adaptability allow it to penetrate, at least occasionally, into the centre of large cities. It happily hunts on tiny scraps of suitable habitat, such as factory carparks, lawns, and the roofs of office blocks. It is highly territorial in summer, and even in winter large numbers of individuals defend patches of ideal habitat, such as a stretch of lowland stream. Other individuals forego a territory and roam the countryside, sneaking into patches defended by others. Most birds forage alone. Whether they are territorial or non-territorial, many non-breeding individuals congregate at night in communal roosts, a characteristic feature of wagtail ecology. These roosts appear in a variety of situations, but one favourite habitat is extensive reedbeds, upon which hundreds, and sometimes thousands, of wagtails converge. Individuals, pairs or small groups usually approach with bounding flight from all points of the compass, call loudly a couple of times, then plummet headlong into the reeds. In the daytime, White Wagtails leave the reedbed to feed in open situations. This individual, so picturesquely captured in a stand of* Phragmites, *has just been disturbed from the shores of a pool and has taken refuge on a handy perch.*

[*Motacilla alba alba*, Hortobágy National Park, Hungary.
Photo: Günter Ziesler]

J. B. Wood found that Yellow Wagtails wintering in Nigeria flew en masse to the roosting site, where they circled and then dived steeply into the vegetation; at dawn, they left the site in waves. At this site, the wagtails that held daytime feeding territories joined the communal roost later and left earlier than did non-territorial flock-feeders.

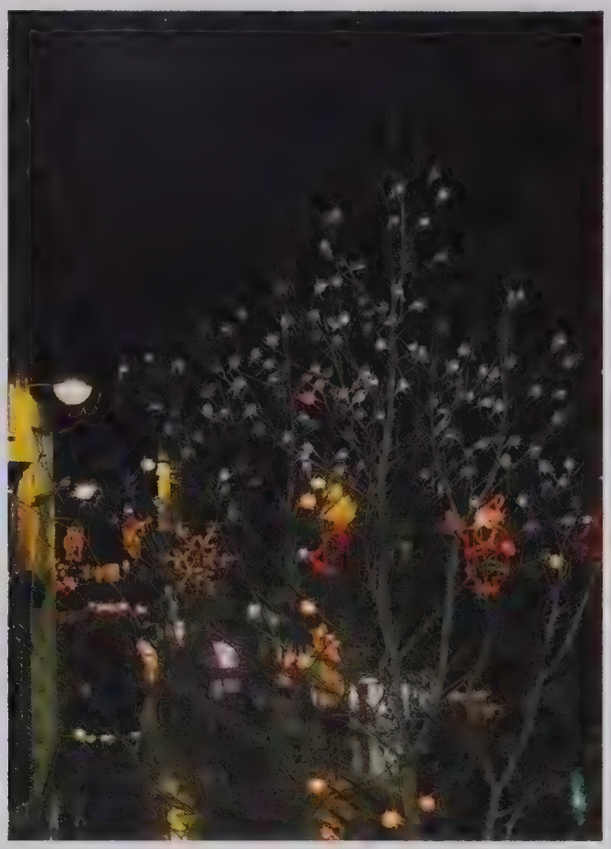
Roosts can contain the same individuals for several weeks or months during the non-breeding season. At other times, however, there can be a high turnover of attendees, presumably as passage migrants stop for a day or two and then migrate farther. At the Berkshire White Wagtail roost, winter visitors and passage migrants arrived at the end of September, with the main passage occurring during October. Wintering numbers reached a peak in December and early January, and by late March and early April many birds had left. Locally breeding wagtails used the roost during the summer, even during the nesting season.

Wagtails and pipits roost in tall aquatic vegetation, such as reeds (*Phragmites*) and sedges, including papyrus (*Cyperus papyrus*), or in trees or sometimes in or on buildings. Both Water and Red-throated Pipits favour reeds, sedges, bulrushes (*Typha*) and grass, as do Yellow and Cape Wagtails. The last two species will also roost in sugar cane, as well as in trees and shrubs such as palms (Arecaceae), figs (*Ficus*), gums (*Eucalyptus*), pines, planes (*Platanus*), and mangroves growing in shallow water. Grey Wagtails prefer bushes or trees overhanging water, but sometimes sleep in sugar cane or reeds, or away from water in trees or on buildings; individuals may roost singly in crevices in stonework, such as under bridges. In Asia, Citrine and Forest Wagtails commonly roost in sugar cane, reeds or mangroves. Urban areas, being generally warmer during the night-time than are more open areas of countryside, not infrequently attract motacillids for roosting. White, African Pied and Cape Wagtails often roost in trees in town and city centres, as well as on or in buildings such as factories and greenhouses, and under bridges. The African Pied Wagtail has been recorded as roosting on yachts in Uganda and on small boats in Kenya.

Any site selected for the purpose of roosting is often used in successive winters over many years. In Nigeria, however, Wood found that Yellow Wagtails frequently changed their roost-sites, attributing this to the probability that predators had learnt to exploit a regular roost.

The practice of communal roosting has been thought to offer the birds additional protection from predation or, alternatively, to serve as an "information centre" whereby the individuals present can learn of the whereabouts of good food sources. P. Ward and A. Zahavi, in 1973, suggested that mixed-species roosts might occur where good roosting sites were limited or where one species benefited in some way, other than by gaining knowledge about food supplies from the other species. They argued that individual species within mixed roosts could still use these as "information centres", enabling them to gain knowledge about the location of food. They also contended that, when roost-members are apparently able to find adequate food with no difficulty, the roost should be seen as a form of "insurance" against the risk of losing a hitherto good feeding area. Autumn roosts of migrating wagtails and pipits may be of some benefit to newly arrived individuals, by providing them with the opportunity to feed with birds that have been in the vicinity for longer and that know where to find food locally. They may also enable dispersed motacillids to join up with others for the onward flight.

By roosting together, birds may be better protected from predators. This is because, with a large number of birds all in one place, one or more individuals will be alert at any given time and, if alarmed, their calls are likely to alert the others, at least those close by. For wagtails, communal roosting is certainly likely to confer an advantage on dominant birds, those in the middle of the roost. These will be better protected from predators.



Y. Yom-Tov recorded an interesting disadvantage of being perched in a low position in a communal roost. Individuals on lower perches may have their plumage damaged by droppings from those above. Experimentally, he tested the effect of droppings on the plumage of captive Common Starlings (*Sturnus vulgaris*) and found that the uric acid reduced the water repellency of the feathers, thereby rendering the birds more vulnerable to wetting and chilling.

Heat conservation may be a further advantage of communal roosting. Preferred roost-sites provide good shelter, thus minimizing energy loss. Moreover, dominant individuals in the mid-

*The **Mountain Wagtail** is a crisply patterned species so strictly tied to freshwater waterways that it can be classed as a habitat specialist. It likes exposed rocks and gushing water, regardless of altitude, and it is hardly ever seen away from the banks of fast-flowing streams and rivers in forested areas, although it does sometimes venture into more open habitats if its competitor, the African Pied Wagtail* (Motacilla aguimp), *is absent. When disturbed, the Mountain Wagtail usually flicks a short way along its chosen stream, calling loudly, until it alights on the branch of a tree, wagging its tail in classic wagtail fashion.*

[*Motacilla clara torrentium*, Mt Kenya, Kenya. Photo: Marc Guyt/AGAMI]

dle of a roost could be warmer than those younger or more subordinate birds at the edge. Wagtails perch apart from their neighbours, rather than huddling together as do Common Wrens (*Troglodytes troglodytes*). At a roost containing 200 White Wagtails of the subspecies *yarrellii*, the median inter-neighbour distance was found to be 17 cm, with a minimum distance of 7 cm. This did not change, whatever the weather, and these distances remained the same when the size of the roost changed. It is probable, therefore, that the wagtails gained no benefit from any increase in temperature that could result from huddling within the roost. Wagtails that roost within factories or greenhouses and on buildings in towns and cities will benefit, as the ambient temperature at all these sites, as mentioned above, is warmer than that found in and around trees or bushes out in the country.

Possibly, the roost also fulfils some social need through allowing interactions between individuals of a species. If the weather turns severe, information gained in the roost may prompt birds to fly farther south, and the roost itself will facilitate the formation of migratory flocks. An element of learning, of behaviour, calls or song, may also be involved. In addition, the roost may also have an important function in the process of mate selection in the late winter.

Maintenance of the plumage and comfort behaviour are fairly routine activities among the Motacillidae. Preening is undertaken frequently, and head-scratching is by the indirect method, with the leg brought up and over the wing. Bathing is carried out in shallow water. Sun-bathing is not well documented for the family, but it has been observed occasionally. Grey Wagtails are described as sunning by adopting a crouched posture on rocks or pebbles, and then spreading the wings, cocking the head backwards and slightly raising the tail. Some of the *Anthus* pipits are known to perform anting, by applying the insects directly to the plumage.

Although small-scale communal roosting is found throughout the family, the only motacillids known to form large roosts are members of the ***White Wagtail*** *complex. The British form, known as the "Pied Wagtail", seems particularly fond of roosting in city centres, either in trees or around rooftops. Individuals, sometimes of more than one species, often converge from farmland sites many miles away to reap the benefits of roosting together. The specific nature of these benefits is difficult to be sure of, but it is likely that some combination of favourable microclimate, predator avoidance, and information transfer can explain the phenomenon.*

[*Motacilla alba yarrellii*, Norfolk, England. Photo: Chris Knights/Ardea]

Voice

Although the motacillids are not great songsters, there is considerable variety in their voices. Indeed, in the case of the pipits, the calls or songs, or both, are very often important aids in identification of species. Motacillids often call when they take off or are flushed. They also give contact and alarm calls.

Calls are simple monosyllabic or disyllabic notes, or occasionally trisyllabic utterances. Typically, the take-off and flight calls are variations of sounds that can be transliterated as "teez", "chip", "tsit", "tsip", "phisst", "tseet", "twee", "dweet" or "wheet". The quality of this note is variable. That emitted by Blyth's Pipit (*Anthus godlewskii*) and the Cape Longclaw is harsh, that of the Olive-backed Pipit is hoarse, the call given by Short-

Pipits are not noted to be aggressive birds but disputes do arise over territory boundaries. These photographs seem to capture a disagreement between one ***Hellmayr's Pipit*** *and another regarding the ownership of a coveted fence post. It is common for pipits to sing strongly at one another, or to embark on prolonged song-flight duels, but it is rare for them to come to blows. Most conflicts are resolved by posturing and vocalizing, and when fights do escalate they usually involve little more than a momentary aerial grappling.*

[*Anthus hellmayri dabbenei*, Laguna Rocha, Riviera, Uruguay. Photos: Johannes Ferdinand]

For all their beauty and popularity, wagtails are pugnacious creatures. Contests between adult males can be violent affairs. The most volatile and combative members of the family belong in the Motacilla alba *complex, including the* ***White-browed Wagtail****. Non-breeding individuals battle over foraging patches, and in the breeding season their testosterone level rockets up. They become infuriated by the merest glimpse of their own reflection; they spend minutes on end attacking window panes, shiny hubcaps and mirrors; and when they encounter a real intruder, they are soon wrestling heedlessly on the ground.*

[*Motacilla maderaspatensis*, India. Photo: David Tipling/ Windrush]

tailed and Bush Pipits is nasal, and that of the Forest Wagtail is metallic. The Meadow Pipits's call is soft and thin, whereas the Sokoke Pipit's is loud and high-pitched. The note can be sharp and often explosive, as demonstrated by the Rock, Grassveld and Long-billed Pipits and the Cape Wagtail, or it can be drawn out into a "chrzeep" or "dzeep" sound or, as with the Yellow and Citrine Wagtails and the Red-throated Pipit, be extended into an almost disyllabic "pseeeow" or "pseeeeeu".

Sometimes, the call note is repeated two or three times. The Cape Wagtail, for example, calls "tsee tsee", the Bush Pipit utters a nasal "tseep tseep tsseep", and the Meadow and Rosy Pipits give a thin, squeaky "tsip tsip tsip". Likewise, many wagtails have disyllabic take-off and flight calls, likened to "chizzik", "tschizzick" or "zittick". This can be harsh, as with the White Wagtail, or shrill and loud, as with the African Pied Wagtail's "tu-weee", or metallic and high-pitched, as with the Grey Wagtail. In the Afrotropics, some of the *Macronyx* and *Hemimacronyx* species utter a softer or whistle-like disyllabic call, as typified by the rich rising "youee" or the descending "eeoo" of Sharpe's Longclaw. Alarm notes of motacillids tend to be shrill and loud, but are sometimes softer. The White Wagtail, for instance, utters a harsh "chick" when alarmed, whereas some longclaws give a cat-like "meeow" and the Rosy Pipit a mournful squeak. Several species make sparrow-like chirps when alarmed. These are similar to the "chirrup" calls uttered from the age of five or six days by the nestlings of some motacillids.

For any species, of course, these short vocalizations vary, often according to the individual's activity and the degree of alarm. For example, the monosyllabic "chip" of the Buffy Pipit is sometimes extended into a disyllabic "chipip" or a trisyllabic "chipipip". Tawny Pipits utter a loud "tseeu" call on take-off, a "tseep" in flight and a shrill "sree" when alarmed, as well as a high-pitched "tji tji tji". The common call of the Yellow-breasted Pipit is a whistled "tseeu", but this species utters a rapid and continuous "chick chick chick" when alarmed. In the latter situation, the Yellow-throated Longclaw makes a loud piping "twip pipipipipipipi", the "pi" note being repeated up to nine or so times. Motacillids emit soft contact calls when on the ground or perched, but the vocalizations become louder on take-off, or shrill and repeated when the individual is in a state of high alert. The Mountain Pipit, for example, has a soft "tuchit tuchit" when perched, a louder "chiri" or "psiu" flight call and a "twit twit twit" alarm call.

Additional sounds are occasionally made. At well-studied roosts of *yarrellii* White Wagtails in the UK, low-level crackling noises have been reported. These have been likened to the sound made by the crumpling of a piece of cellophane, and are apparently produced by soft clicking of the mandibles. The sounds are thought to be made by individuals defending sheltered positions within the roost.

The songs of the members of this family are generally simple and often rather monotonous. The song of the Buffy Pipit has been described as a dry and monotonous series of notes, and that of the Yellow Wagtail as a prolonged high-pitched twittering. On the other hand, the Cape Wagtail's song has struck some listeners as being melodious and not unlike that of a canary (*Serinus*), and that of the Paramo Pipit as having a thrush-like quality.

Rather typical of the family are songs consisting of a repeated series of call-like notes. In the case of the Long-billed Pipit, these are delivered in a random and disjointed sequence, whereas the Grassveld Pipit repeats phrases of three to five notes every few seconds. The song of Sharpe's Longclaw is a thin series of whistles, rising in pitch, or repeated "sip" notes, while the loud melodious song of the Striped Pipit is a sequence of whistled phrases, each lasting 2-5 seconds, with a 1-second pause between them. The sweet-sounding song of the Yellow-tufted Pipit is a repetition of disyllabic notes, "whee-tsreeee", the second note trilled. Various motacillid songs end with a wheeze, as that of the Rosy-breasted Longclaw, or with a trill usually falling in pitch, as in the case of the Grey Wagtail and the Meadow Pipit.

The Upland Pipit has a song that is strikingly different from those of its congeners. It consists of two notes, "seetyu seetyu" or "tyusee-tyusee", repeated several times, and is reminiscent of that of a Great Tit (*Parus major*) but slower and less brisk. This species also sings a long-drawn monotonous, whistling "wichee wichee wichee", the notes being repeated up to 15 times; it has been likened to the sound of a saw being sharpened. In contrast, the song of the Olive-backed Pipit has been likened to that of a Common Wren, while that of the nominate race of the Pechora Pipit consists of buzzing lark-like trills or trills resembling those made by a Wood Warbler (*Phylloscopus sibilatrix*).

Sunning behaviour in motacillids has received paltry coverage in the ornithological literature, but this does not mean it is an uncommon event. This ***White Wagtail*** *has been captured in classic sunning posture, and it is likely that all members of the family strike this pose when suitable conditions arise. Sunning is thought to play a role in maintaining feather quality and controlling parasite load. It usually takes place when a bird, induced by the warmth of a sheltered spot, spreads its wings and tail, raises the feathering on its abdomen, and tilts its head away from the sun. As a result, direct sunlight penetrates the largest possible surface area of plumage.*

[*Motacilla alba alba*, Sohar, Oman. Photo: Hanne & Jens Eriksen]

The two other races of this pipit, *menzbieri* and *stejnegeri*, have a weird mechanically whirring, buzzing song, in the case of the latter sometimes likened to the dry rasping jingle of an *Emberiza* bunting or even recalling the drumming of a Common Snipe (*Gallinago gallinago*).

Wagtails and pipits deliver their songs from a perch, such as a fence post, termite mound, rock or tree, or high in the air, or during the descent stage of an aerial display (see Breeding). The Rosy Pipit's song comprises a twittering phrase while the bird is rising into the sky, followed by long series of pleasant "tsuli-tsuli-tsuli" notes as it descends on outstretched quivering wings, these fading as it nears the ground. Above the prairies of North America, Sprague's Pipit sings incessantly while high in the air, its song being variously interpreted as a sweet, thin jingling series, descending in pitch, of repeated "ching-a-ring" or a descending series of musical "tzee" or "tzee-a" notes. In Africa, where the Grassveld Pipit sings in a circular display flight, the related Paddyfield Pipit ascends with a sparrow-like "chirrup", and then gives a disyllabic "diee" series as it hovers, before making a silent descent. It then rises once more. In the grasslands of the Neotropics, the Yellowish Pipit utters short "tsit" calls as it climbs, but pours forth a long slurred song as it glides down. As a final example, the Madagascar Wagtail's melodious song, a trisyllabic, slightly trilled "tree treeoo", usually repeated several times and followed by a melodic phrase, is delivered from the ground, from a raised perch or in flight.

There is some evidence that mimicry is incorporated into motacillid song. T. Farkas found that some longclaws, when alarmed, imitated other birds. Furthermore, C. J. Vernon believed that the songs of the Striped Pipit and the African Pied Wagtail were sufficiently complex to suggest that they may sometimes include imitations.

Food and Feeding

All members of the Motacillidae family feed largely on small invertebrates. The sharp and wide but long and pointed bill of the pipits, longclaws and wagtails is perfectly adapted for picking prey from soft sand or mud, among rocks and pebbles or in short vegetation. A huge array of invertebrates is eaten. Insects predominate in the diet, but a wide variety of other arthropods, ranging from spiders and other arachnids to myriapods, worms, small terrestrial, freshwater or marine molluscs and crustaceans are also consumed. Among insect prey, various fly (Diptera) larvae and adults, small beetles (Coleoptera), crickets and grasshoppers (Orthoptera) and larval and adult moths and butterflies (Lepidoptera) are especially important. Among other important insect prey are hemipterans, including both true bugs (Heteroptera) and cicadas and aphids (Homoptera), mantids (Mantodea), termites, especially winged ones, and ants (Hymenoptera), while aquatic insects, such as mayflies (Ephemeroptera), feature prominently in the diet of riverine species. Larger invertebrates, such as crabs, are sometimes caught, and vertebrate prey occasionally taken include amphibian tadpoles, lizards and fish. Seeds and other vegetable material are eaten by many species, but they form only a small part of the diet. Grit is also ingested, as an aid to digestion.

For many motacillids, there is still rather little information available on the diet other than the fact that small insects and other invertebrates are eaten. The South American species have been little studied, and virtually nothing is known of the diet of some African species such as the Long-legged (*Anthus pallidiventris*), Long-tailed and Mountain Pipits. Relevant observations on Madagascar Wagtails are also few. In contrast, the diets of some motacillids, notably the White, Yellow and Grey Wagtails, have been studied in great detail.

Direct observations of birds actively feeding, or carrying food to a nest, have provided some data on prey species taken, but in most cases these involve mainly larger and, therefore, readily identifiable items. Otherwise, there are three methods for carrying out quantitative analyses of avian diets. The first involves the collecting of a large sample of individual birds and analysing the stomach contents, but this method, because of the potential conservation implications, has become much less acceptable among ornithologists in recent decades. Examination of faeces and the identification of any chitinous material, such as mouthparts, head capsules, leg fragments and wings or wingcases, is a useful second method. Both adult faeces and the faecal sacs of young can be collected for such analysis, and this method does not have any adverse impact on the birds. The third method involves the use of neck collars or ligatures, which are placed around the neck of nestling birds in order to prevent them from swallowing food; the prey can then be collected from the nestlings and analysed. Provided that the collars are used carefully, and for a limited amount of time, this practice poses little danger to the young.

Stomach and faecal analyses are useful techniques for identifying and quantifying prey, but they do not detect such quickly digested items as flies and homopteran bugs or other soft-bodied wingless invertebrates and can, therefore, misrepresent the proportional importance of some prey. If the bird remove the insect's wings, as has been reported for wagtails taking gadflies (Tabanidae), dragonflies and damselflies (Odonata) and butterflies, these insects may then be under-represented in faecal analysis. Careful application of neck collars can be a means of showing exactly what prey are fed to the young. Whatever the method employed, samples must be collected over a sufficient time period to identify the full range of prey and any seasonal changes in the diet. Limited samples can present an erroneous picture.

Analyses of stomach contents have been undertaken for many motacillids, but the samples generally have been rather few, and from limited locations and seasons. Most stomachs contain a wide diversity of prey items. Neck-collar studies, which have also been widely carried out, have demonstrated, for example, that adult Diptera formed 70% of the food items brought to Meadow Pipits nestlings in a study area in England, a further 19% of items being insect larvae. Similarly, in an urban study area in Japan, this method revealed that both White and Japanese Wagtails also fed largely on dipterans: flies, especially craneflies (Tipulidae), formed 85% and 88% of the prey fed to chicks of the two respective species. Spiders accounted for much of the remaining prey identified, although Japanese Wagtails took some mole-crickets (*Gryllotalpa*), which were significant in terms of weight. Away from urban areas, along rivers, mayflies and stoneflies (Plecoptera) were shown to be more important than flies as food for Japanese Wagtails.

The importance of flies and aquatic insects in the nestling diet of Grey Wagtails has been demonstrated by several neck-collar studies. In one such study, carried out by V. D. Sonin and N. F. Anuchina at Lake Baikal, in north-central Asia, the adults fed the nestlings with a range of invertebrate prey, but over 54% of items were, in order of abundance, mayflies, stoneflies, dipteran flies and caddis flies (Trichoptera). Far to the west, in the Tien Shan Mountains, A. F. Kovshar' found that mayflies, stoneflies and caddis flies dominated the diet of nestlings in late June and early July, making up 85% of food items, but they represented only 5·4% in late July, when dipteran flies were most important, accounting for 32·8%. In the Czech Republic, S. Bureš and M. Kral noted that 90% of 944 prey items fed to nestling Grey Wagtails were flies, mayflies, stoneflies and beetles, in equal numbers, with caddis flies and homopterans each comprising just over 3%; almost 69% of all prey items were adult insects. In a second study in the same country, undertaken a few years later by Bureš, a sample of 496 prey items comprised 36% dipterans, 26% stoneflies, 13·5% homopterans and 8·5% caddis flies, with larvae of aquatic insects representing less than 7% of the nestling diet; aquatic larvae were more important earlier in the breeding season, when there were more large larvae in the river, but these disappeared as the season progressed and as adults emerged. In a Swiss study of the chick-feeding rate of Grey Wagtails, L. von Schifferli found that dipterans were the most important prey numerically, at 43% of items, with stoneflies, mayflies and caddis flies also featuring highly in the diet. These insects were all of aquatic origin, but larvae and adults of a variety of terrestrial insects, as well as a few spiders, were also eaten.

In 1985, both faecal analysis and neck collars were employed by S. J. Ormerod and S. J. Tyler, in Wales, in an attempt to determine the relative importance of different prey for adult and young Grey Wagtails in the breeding season. Diets of adults and nestlings were found to be similar, with adult flies the commonest items. These included small bristly flies (Empididae), hoverflies (Syrphidae), winter gnats (Trichoceridae), shore-flies (Ephyridae), craneflies and non-biting midges (Chironomidae). Adults and young consumed very similar proportions of aquatic prey, in each case representing a quarter of the diet, although nestlings ate more caddis larvae and adults more mayfly nymphs. The importance of the aquatic prey, however, is underestimated when assessed in terms of the numbers, rather than the size and weight, of prey items. Caddis larvae and stonefly and mayfly nymphs tend to be larger items than chironomids or other flies. Further studies were undertaken in Wales in 1986 and 1987, at both acidic streams, where aquatic insects, notably mayflies, are reduced, and non-acidic streams in broadleaf woodland, coniferous woodland and moorland. Again, the numerical importance of flies in the diet of both adult and nestling Grey Wagtails was demonstrated. Adult flies contributed 55-64% of items taken by adults and 23-49% of those fed to the young. Nineteen fly families were identified, all having larvae that live in wet, decaying vegetation or in moor-

The preen gland, also known as the uropygial gland, is located at the base of the tail. It produces an exudate of oil, which birds use to maintain their plumage. The gathering of this oil with the bill during preening is a routine procedure found in all birds, demonstrated expertly by this ***Yellow Wagtail****. The importance of this behaviour is self-evident: frequent waterproofing allows plumage to resist heavy rainfall and the occasional accidental drenching. It is perhaps especially important in birds like wagtails, which are not averse to getting wet.*

[*Motacilla flava flava*, Ma'agan Mikhael, Israel. Photo: David M. Cottridge/ Windrush]

Like most other passerines, pipits and wagtails frequently bathe. They dunk their bellies in shallow pools and flutter their wings so that water droplets splash over the body. There is little doubt that the policy of regular bathing pursued by this ***Red-throated Pipit*** *and* ***Yellow Wagtail*** *owes much to the requirement for clean and functional plumage, but it is also possible that bathing functions in thermoregulation. Most motacillids spend their entire lives in the full glare of the sun, away from shade and shelter, and this must mean that they get very hot, at least in tropical or subtropical climes. Presumably, plunging the plumage into cool water must produce the twin benefits of immediate dousing and subsequent evaporation, both of which must lead to a welcome reduction in core temperature.*

Bottom: *Motacilla flava flava*, Al Ansab, Oman. Photo: Hanne & Jens Eriksen/Nature Picture Library]

land soils. Some differences were apparent between the diets of the two age-classes and between sites in different habitats. The most marked finding was that, at sites in broadleaf woodland, moth caterpillars were frequent in the diet of adults, in which they formed 18% of items by number, but particularly abundant in that of nestlings, in which they made up almost half of all items recorded. At these sites, flies were correspondingly of less importance. In all habitats, spiders were more important in the diet of nestlings than in that of adults. Aquatic prey made a smaller contribution to the adult diet on acidic streams than they did on non-acidic streams. This was due mainly to the greater exploitation of mayflies on non-acidic streams.

The importance of bankside land use was clearly demonstrated during this study. Using a sweep net to catch insects in the riparian zone, the researchers found that prey availability on upland streams was greater where broadleaf woodland bordered the banks than in places where banks were bordered by conifers or moorland. In the same study, water traps also revealed that insects were more numerous along streams bordered by broadleaf trees than on those with conifers, although in this case insect numbers on moorland streams were also high.

C. Marti and C. Breitenmoser-Würsten carried out a dietary study of Grey Wagtails in Switzerland during the breeding season, and their results proved very similar to those of the earlier Swiss study, as well as those found in the Welsh study and in the second of the Czech studies. Flies and stoneflies were universally important, making up 40-50% and 10-20%, respectively, of food items in all studies except that in the Czech Republic, where fewer flies were taken. Mayflies were especially important for nestlings in Switzerland and the Czech Republic, as were caddis larvae in Wales.

One researcher in eastern Europe found that, although the young and the adults had similar diets, that of young birds was initially dominated by soft-skinned larvae of mayflies, stoneflies and caddis flies, and diptera. It gradually progressed to invertebrates with harder chitinous exoskeletons or wings. This bears comparison with the dietary habits of the Tree Pipit. Adult Tree Pipits feed largely on beetles, but they feed fewer beetles to the chicks, instead providing the latter with more grasshoppers, flies, caterpillars and spiders.

Results from a brief dietary study, using faecal analysis, of Mountain Wagtails and wintering Grey Wagtails on rivers in Ethiopia showed that both species preyed mainly on aquatic insects, especially flies of the families Chironomidae and Empididae. Adult flies of these two families constituted, numerically, 53% of prey items taken by Mountain Wagtails and 33% of items taken by Grey Wagtails. Mayfly adults and, especially, nymphs were important to both species, accounting for 26·5% of the former's diet and 34·9% of the latter's. Lepidoptera and beetle adults and larvae made up 11% of items taken by Mountain Wagtails, and beetles 15·3% of those taken by Grey Wagtails. Fly larvae and blackflies (Simuliidae) formed only 4% of the Mountain Wagtail diet, whereas chironomid and simuliid larvae formed 11% of the Grey Wagtail's food. Caddis flies and stoneflies were taken in small numbers by both species. In addition, Mountain Wagtails were also observed to catch large dragonfly nymphs, butterflies and tadpoles, and a Grey Wagtail caught a small orange pierid butterfly of the genus *Pholotis*.

Most motacillids investigated appear to be very catholic in their choice of insect and other arthropod food, and also to be opportunistic. They all take a wide range of prey, the composition of which depends on the abundance of different arthopods, the size of the bird, and the habitat, location, season and weather. Insects are undoubtedly the most important food for all species of pipit, longclaw and wagtail, and certain orders of insects feature most prominently in the diets of many of them. For example, orthopterans and coleopterans are the most important prey for many terrestrial motacillids. They form a major component of the diet of longclaws. Grasshoppers and beetles were found in 69% of 51 Grassveld Pipit stomachs. Buffy Pipits showed similar prey preferences, with beetles found in 76% of those stomachs examined and grasshoppers in 69%; moths and hymenopterans were the next most numerous items. Plain-backed and Buff-bellied Pipits also favoured grasshoppers and beetles, while beetles, grasshoppers and ants were numerically the most important prey items for Tawny Pipits in Moldova, Crimea and Kazakhstan. Adult Tree Pipits consume large

Pipits, wagtails and longclaws are birds of open country, so it comes as no surprise that they are a falcon's favourite snack. Indeed, Meadow Pipits (Anthus pratensis) *form 70-80% of the diet of Merlins* (Falco columbarius) *on some British moorlands. Given the scale of this threat, it is of vital importance that motacillids maintain a watchful vigilance for raptors. All this goes some way to explaining why a* ***White Wagtail****, of the race sometimes split as the "Amur Wagtail", is watching the skies with such interest through its beady eye. Admittedly, a cynic might suggest that it is actually the other eye that is peering downwards at an even smaller victim!*

[*Motacilla alba leucopsis*, Long Valley, Hong Kong. Photo: Martin Hale]

Pipits are not the most awe-inspiring of songsters, but they make up for their lack of melody and repertoire with gusto and sheer persistence. Like most of its genus, the ***Tawny Pipit*** *sings either in flight or from a perch. In both cases, the song is a monotonously simple, constantly repeated phrase, a rolling "tsirluii" or similar variant, each statement lasting less than a second, and followed by a few seconds of silence. This simple format is typical of larger pipits, while smaller species often give a more complex rendition. The* ***Tree Pipit****, for example, tends to have a much longer and more complex song, lasting 8 seconds, followed by a much longer pause. The song itself is a series of trills and repetitive notes, with the most distinctive and far-carrying section (often the only one heard) being a terminal sequence of long slurred notes, sounding like "chea chea chea". This distinctive and formulaic outpouring is often accompanied by a parachuting song flight. During this flight, and unlike the Meadow Pipit* (Anthus pratensis) *of nearby fields, it dangles its legs during descent. Another straightforward distinction between these species is useful when the distinctive songs are out of earshot: Tree Pipits almost invariably land back in a tree, whereas Meadow Pipits usually drop all the way to the ground.*

*The **Rosy-breasted Longclaw** is typical of its genus in producing most of its territorial songs from an exposed perch. It sings a simple repetitive loud, metallic phrase, "wee-tjihwee-tjih", or else a series of squeaky whistles ending in a drawn-out wheezy note: "pink-pink-pink-zheenk". These sounds are designed to carry far across the open country of the African savanna. At times, the song may alternatively be given during a brief, fluttering display flight.*

[*Macronyx ameliae wintoni*, Masai Mara National Park, Kenya. Photo: Muriel Nicolotti/Bios]

numbers of beetles, especially weevils (Curculionidae), carabids, scarabaeids and elaterids, whereas they feed their chicks with fewer beetles but more grasshoppers, flies and caterpillars; grasshoppers made up 63% of the nestling diet in one study. Beetles formed 14%, 22·4% and 31·2% of prey items taken by Meadow Pipits in Wales, Norway and Germany, respectively.

Dipterans and adult or larval moths and butterflies are also common prey for many motacillids. Flies and their larvae are taken in huge numbers, notably by smaller species such as the Meadow Pipit, as well as the Grey Wagtail. In three study areas in Britain, Norway and Germany, dipterans formed, respectively, 49%, 18% and 23·4% of the food items taken by Meadow Pipits. Caterpillars are readily eaten by most motacillids, but adult butterflies and moths are more difficult to catch unless they are resting in vegetation, as in cool or wet weather, or are newly emerged. Wagtails are more adept at capturing butterflies than are other motacillids. As has been observed in Ethiopia, when a Grey or Mountain Wagtail seizes a butterfly, it often removes the insect's wings before eating it or feeding it to its young. Other species, such as the African Pied Wagtail, do the same. On the Okavango River, in northern Botswana, these wagtails discarded the wings of various butterflies, depositing them on sand by the river. T. B. Larsen identified the wings as belonging to four species of white butterfly of the family Pieridae, the members of which are supposedly distasteful to birds, one species of lycaenid, two nymphalids, including the large strong-flying *Charaxes phaeus*, and a species of hesperid.

Worms appear to be eaten only rarely, although they may be overlooked in stomach and faecal analyses. Meadow Pipits and wagtails that forage at sewage works, especially in the non-breeding season, take many small red worms of the species *Lumbricus rubellus*. Annelid worms are included in the diet of African Pied Wagtails and polychaete worms in that of Rock Pipits.

Aquatic insects, both larvae and winged adults, are major items in the diets of all riverine species. Mayflies, caddis flies, stoneflies, and chironomids and other dipterans, many of aquatic origin, have all been identified as the most important prey for Grey Wagtails in the breeding season in studies in Wales, Switzerland and the Czech Republic. Motacillids living by rivers, lakes, marshes or other wetlands sometimes prey on damselflies and dragonflies, even relatively big species such as the southern hawker (*Aeshna cyanea*). These are large, energy-rich food items for a wagtail, but offset against this are the energetic costs incurred in catching and dealing with such prey. The bird must first immobilize the insect, and then break up or manoeuvre it to enable the food to be swallowed. Any motacillid that catches a large dragonfly or damselfly, or other large prey such as a grasshopper, usually beats the insect repeatedly on the ground or a rock in order to kill it. It may then dismember the prey by hammering at it with the bill, or it may remove the wings. Grey Wagtails, when they caught damselflies of the two species *Agrion splendens* and *A. virgo*, were observed to remove all four wings of each insect before presenting the food to nestlings or juveniles. Dragonflies emerging from nymphs are easily captured, and a mass emergence provides a useful, if temporary, source of food.

Other than spiders, which feature fairly commonly in motacillid diets, a number of arachnids are eaten by the members of the family. Ticks (Acarina) are possibly eaten by Cape Wagtails, for example, and scorpions (Scorpiones) have been recorded as prey of Long-billed Pipits.

Crustaceans and marine molluscs represent important food for coastal species. During the winter months, when grassland on its subantarctic island is covered with snow, the South Georgia Pipit relies on small marine invertebrates along the shore and around tidal pools. The diet of Rock Pipits living on the coasts of north-west Europe includes small isopod crustaceans such as sea slaters (*Ligia*), amphipods such as sandhoppers (Talitridae), and small crabs. Cape Wagtails have been watched as they caught fiddler crabs at low tide on a South African estuary; the wagtails were seen to beat each crab against a stone until its appendages were shed, thereby gaining access to the claws, legs and carapace. Similarly, African Pied Wagtails sometimes prey on small ghost crabs on the Kenyan coast, and Australasian Pipits have been observed to feed on crabs in New Zealand.

While freshwater and terrestrial molluscs are eaten by many motacillids, marine molluscs, such as dog-whelks (*Nucella*) and,

*Most wagtails and pipits call frequently, especially in flight, with simple notes of the style "swit", "chirp" or "chirrup". These flight calls are one of their most characteristic features, and often betray their presence as they fly high over a prairie or a city centre, where they would not otherwise have been noticed. Unlike pipits, however, wagtails sing rather infrequently, although when they do they have a surprisingly sweet song. The **African Pied Wagtail** is typical in producing a sustained garbled series of whistling and piping notes, involving lots of different note types, and, according to some listeners, much mimicry.*

[*Motacilla aguimp vidua*, Kruger National Park, South Africa. Photo: Johannes Ferdinand]

*Like all its relatives, the **Striped Pipit** undertakes most of its foraging on the ground. It subsists on a diet largely comprising insects and their larvae, all of which it catches by busily walking to and fro and pouncing on food items detected by sight. Its bill is ideally suited to the task of snatching at mobile prey, being long, sharp and pincer-like. Unlike most pipits, this species often forages among and over rocks; indeed throughout much of its range its distribution seems rather tied to the presence of rocky habitat.*

[*Anthus lineiventris stygium*, Marondera, Zimbabwe. Photo: Peter J. Ginn]

particularly, small periwinkles (*Littorina*), form a very significant part of the diet of Rock Pipits in Europe, notably in the winter months. So, too, do isopods of the genus *Idotea* and, in the late summer, amphipod hoppers (Talitridae). In the Netherlands, groups of wintering Rock Pipits fed almost exclusively on the mollusc *Asiminea grayana*, while the winter diet in Norway was mostly of crustaceans. Cape Wagtails foraging among seaweed-covered rocks along the southern coast of South Africa may also take small crustaceans or molluscs, but kelp flies (Coelopidae) are a favoured prey.

Vertebrates are comparatively rarely taken by motacillids. Amphibian tadpoles are eaten by Mountain and Grey Wagtails, and probably by other riverine and wetland species, and small frogs are eaten by Rosy-breasted Longclaws. Fish have been reported as prey for a number of species, ranging from Rock and Water Pipits to White, African Pied and Grey Wagtails. One Rock Pipit was seen to carry several rocklings, probably of the species *Gaidropsarus vulgaris*, which were 2-2·5 cm long, and a sandeel (Ammodytidae) of 5-6 cm; it seems likely, however, that the bird scavenged the fish from the entrance to an Atlantic Puffin (*Fratercula arctica*) burrow, where the food had either been discarded by a puffin or been dropped by one when harassed by gulls (*Larus*). One observer watched a Water Pipit as it caught a fish through a crack in ice, and Grey Wagtails have often been seen to catch fish fry and small minnows (*Phoxinus*), as well as sticklebacks (Gasterosteidae). In south-east England, a White Wagtail also caught perch (*Perca fluviatilis*) fry 3·5 cm long on two consecutive days; it flew off with the fish for its young, on one occasion carrying three fish crossways in its bill. In another instance, the staple diet of young Grey Wagtails bred in captivity was small fish; the female wagtail fed her chicks with the provided minnows, fish fry and a few sticklebacks, ignoring a supply of maggots.

When a wagtail or pipit catches a fish, it repeatedly beats it, in the manner of a kingfisher (Alcedinidae), before swallowing the fish head first. Sometimes, the spines on a stickleback can cause problems. For example, a Grey Wagtail, having caught a small stickleback at a garden pond, first beat it repeatedly on the concrete edge of the pond. It then tried to swallow the prey head first but had great difficulty, perhaps because the fish had managed to raise its spines, and for several minutes the wagtail was in apparent distress, opening and closing its bill, as it attempted to swallow the fish.

Surprisingly, lizards have apparently been reported as prey only for the Madagascar Wagtail, once, and for the Tawny Pipit. In the latter case, the remains of an unidentified lizard were found in a stomach from Kazakhstan, and there is a record of an individual taking a sand lizard (*Lacerta agilis*). Observations suggest that Cape Wagtails possibly capture and eat small chameleons (*Chamaeleo*) on occasion.

Seeds, berries and grit have been found in the stomachs of many pipits and wagtails. Seeds were, for example, found to have been ingested by Berthelot's Pipit and various longclaws, and were present in 12% of 51 stomachs of Grassveld Pipits examined. Meadow Pipits take seeds from a wide range of plants, including the grasses *Poa* and *Alopecurus*, rushes (Juncaceae), sedges, heaths (Ericaceae), crowberry (*Empetrum*), the families Cruciferae and Rosaceae, docks (*Rumex*), goosefoots (*Chenopodium*), flax (*Linum*), eyebright (*Euphrasia*), violets (*Viola*) and figworts (*Scrophularia*). Tree Pipits in Russia had consumed fruits of three species of *Vaccinium* and of elder (*Sambucus*), as well as seeds of violets, Labiatae, chickweed wintergreen (*Trientalis*) and cow-wheat (*Melampyrum*), and of birch (*Betula*) and pine (*Pinus*); aspen (*Populus tremula*) buds and spruce (*Picea*) needles were also taken. Similarly, seeds from a variety of families were found in 9% of 57 stomachs of Australasian Pipits. Clover seeds (Leguminosae) were most numerous, followed by seeds from grasses, and those of the families Compositae, Plantaginaceae, Cyperaceae, Polygonaceae, Labiatae, Cruciferae, Caryophyllaceae, Ranunculaceae and Rubiaceae.

At least a dozen other pipits are known to feed at times on seeds or berries. The New Guinea Pipit (*Anthus gutturalis*), for example, supplements its insect diet with seeds, particularly those of grasses, along with berries and green herbaceous matter. Further, the Paddyfield Pipit has been recorded as eating grass blades, as well as other vegetable matter, in India, and the Water Pipit consumes algae, in addition to other plant material. Among the wagtails, the White-browed Wagtail is reported as eating seeds occasionally.

Vegetable material may be more important at times when insects are scarce, as during the winter months. Seeds were noted in the stomachs of Tawny Pipits mainly at this time. Yellow Wagtails

Lepidopteran larvae constitute one of the principal sources of food of several pipits, including the ***Red-throated Pipit****. In one study, over a quarter of the summer diet of this species was made up of caterpillars. This juicy intake is supplemented by a range of other invertebrate items, including large numbers of beetles and spiders, and smaller quantities of centipedes, molluscs and annelid worms. Although its plumage is relatively modest, this species is the most brightly coloured member of the genus* Anthus.

[*Anthus cervinus*, Mai Po, Hong Kong. Photo: Martin Hale]

eat berries of the saltbush (*Salvadora persica*) and other plant material in their African non-breeding quarters, and White Wagtails sometimes take oat grain in India. The nectar of *Erythrina* flowers is a food source for wintering Tree Pipits in both regions.

Grit is ingested by some motacillids. Of a sample of 304 Meadow Pipits, for example, 131 had grit or small stones in the stomach, most of those with grit being young birds; one individual had as many as 18 stones in its stomach. Grit has been found also in Grassveld, Buffy, Olive-backed and Rosy Pipits, and quartz grains are usually present in the stomachs of New Guinea Pipits. One Grey Wagtail had swallowed ten small stones. It is widely believed that grit is usually taken by birds as a means of helping to break up food. As many motacillids seem not to ingest such material, however, this may not always be its function. It is possible that the grit supplies minerals. Interestingly, feathers have been discovered in a small percentage of stomachs of Buffy Pipits examined in Zimbabwe, and have also been found in those of Grassveld Pipits.

Some members of the family indulge in scavenging or are attracted to artificial food sources. White Wagtails, African Pied Wagtails and Meadow Pipits readily take advantage of crumbs, suet and other household scraps, and African Pied Wagtail have been recorded as feeding on discarded meat scraps. Meadow Pipits have even been seen to take breadcrumbs to their young. During the winter months, Yellow Wagtails and Meadow Pipits often forage for scraps on refuse tips and both are also attracted to supplies of mealworms (*Tenebrio molitor*). In southern Africa, Cape Wagtails frequently visit gardens, where they have been observed to eat raw meat, fat, suet, cheese, hard-boiled egg, mealie meal, cake and bread; this species sometimes becomes tame enough to enter houses and peck at morsels of food on the floor. There are reports of White Wagtails scavenging the remains of dead fish and pecking at the corpse of a gull, and one individual of this species in Norway attempted to feed from strips of meat hung out to dry. Some of the more bizarre reports, from England, involve a Grey Wagtail that entered a fishing-tackle shop in the city of Liverpool and took maggots (dipteran larvae) from trays, and another that visited the polar bear (*Ursus maritimus*) enclosure at Chester Zoo and fed on flies attracted to meat. Others of this species have been watched as they picked insects from piles of feral pigeon droppings and from sacks of grain.

As motacillids are able to capitalize on whatever is temporarily abundant in any habitat, diet inevitably changes throughout the year as different insects emerge and reach peak numbers. Although termites form an important component of the diet of most motacillids in Africa, these insects are available for a limited time. The birds usually prey on the winged termites, or alates, but these emerge only after rain. Changes in diet of the Meadow Pipit occur through the breeding season, as has been demonstrated in studies in Snowdonia, in Wales. Here, the pipits exploited a range of prey species, but flies, especially craneflies, were of particular importance, accounting for 43% of the food intake in April, 74% in May and 47% in June, and declining thereafter. The highest percentage of beetles in the diet was reached in July, and that of hymenopterans and hemipterans in August, while spiders and moth caterpillars were favoured in March; these months coincided with the periods when each of these respective invertebrate groups was available in the highest numbers. Another study of Meadow Pipits, in the English Pennines, revealed interesting differences between the food brought to early broods and that delivered to late broods. The adults supplied first broods mainly with craneflies, which made up 85% of items, with mayflies representing 11%, other adult flies 3%, and fly larvae and stoneflies each 0·5%. Later in the season, when the birds were feeding second broods, craneflies dropped to 41%, whereas mayflies increased to 30% and adult flies and moths formed, respectively, 11·5% and 7·4% of the nestling diet.

Changes in the diet of Red-throated Pipits during the breeding season have also been noted. In north-west Finland, spiders and tipulid larvae formed a large component of the prey in late May to early June, tipulids and mosquitoes (Culicidae) figured prominently in mid-June, while larval and adult hymenopterans, lepidopterans and coleopterans were eaten later in the season. Similarly, in a study of breeding Tawny Pipits, the diet of the chicks was found to change during the course of the fledging period. Newly hatched chicks were fed mostly with grasshoppers, which accounted for 30% of items, and larval and adult moths, which made up 21%, with smaller numbers of spiders and beetles; at 3-6 days they were given a larger proportion of grasshoppers, 58%, while spiders increased to 19% and beetles to 17%; chicks older than 7 days received mainly grasshoppers, which formed 62% of their food. Differential availability

of prey species may be the cause of these dietary shifts. Alternatively, it is possible that the adults select different prey as the young mature.

Of course, details of diet will also vary according to the habitat. For example, wintering Yellow Wagtails that fed around cattle in West Africa preyed mainly on bugs, beetles and flies. Those foraging at cowpats ate beetles, whereas those feeding in lush grass consumed bugs and ants and those along streams exploited the aquatic larvae of flies and dragonflies. After rain, all wagtails fed on winged termites and homopterans.

The two main foraging strategies of all wagtails, pipits and longclaws involve picking prey from the ground or vegetation, and flycatching by plucking insects from the air while in flight. Other strategies, such as hovering, are also used, as are variants of the two primary methods. In Nigeria, for instance, eight distinct foraging techniques of Yellow Wagtails were recognized. The long, strong legs and claws of most motacillids are adaptations for walking on the ground, and all of the species commonly forage in this manner, picking prey from the surface of the ground, from rocks or shoals in rivers, from mud or the water surface, or from vegetation. Pecking rates are very high. Various studies have shown that Pied, Mountain and Grey Wagtails and Rock Pipits take 15-20 food items, and occasionally more, per minute. Rock Pipits have been recorded as taking 33 small periwinkles per minute and 35 larvae of chironomid midges per minute. Although they usually catch readily observed prey, pipits and wagtails will also turn over leaf litter to find food items. Wading into shallow water to pick aquatic invertebrates is a foraging strategy used by most wagtails, and by those pipits and longclaws that favour wetland habitats. Citrine Wagtails will even immerse the head in order to pick up insect larvae. Some members of the family, such as Grassveld Pipits, break up dung to find beetle larvae and other prey, and longclaws use their strong feet and claws to scratch open termite burrows.

Yellow Wagtails are well known for associating with grazing cattle or game, especially in their non-breeding grounds in Africa, where Cape Longclaws are also found in the same situation. The birds feed around the feet of the mammals and benefit from the insects flushed from the grass by the animals' movements. Such behaviour is also common among Tawny, Richard's and Plain-backed Pipits. White Wagtails sometimes take insects from the heads of cattle and deer, and in Germany one was seen to pick for insects while perched on the back of a pig. Associations with humans have also been reported. For example, a Rock Pipit was observed as it followed a man in a tractor who was collecting pebbles on a beach; the pipit picked up sandhoppers and other arthropods that were exposed by the tractor's activity. Similarly, Cape Longclaws will follow a plough and snatch prey items turned over by it. White Wagtails regularly follow machines, even lawnmowers, to take advantage of disturbed or injured insects. In the Azores, the resident Grey Wagtails were drawn to sites on the coast where whalers were cutting up whales, which, in turn, attracted numerous flies.

Several motacillids, such as Tree, Olive-backed and Woodland Pipits, and Forest Wagtails, sometimes forage in trees, where they walk along branches and pick insects from the foliage or other vegetation. Tree Pipits, for example, were observed leaf-gleaning in Portugal and in Africa. Surprisingly, even Rock Pipits have at times been observed to feed in trees.

Picking is used for rather inactive terrestrial prey. When the prey species is more active, however, the bird may dart or run forwards, a strategy sometimes referred to as "darting" or "run-picking", as it pursues and seizes the victim. Another technique involves reaching up or even jumping into the air to snap up flying prey, or flying out from a perch to do so. In South Africa, C. J. Skead observed a Cape Wagtail that fed by standing and facing into a light breeze and snapping up kelp flies as they drifted past.

Aerial flycatching is an important strategy for some wagtails, notably the long-tailed Grey and Mountain Wagtails, which, during the breeding season, inhabit mountain rivers and streams in Eurasia and in Africa, respectively. These two species commonly fly out from a branch or other perch and catch insects over the water. Flycatching is prevalent in warm, sunny weather, when insects are on the wing. On cooler or wetter days, picking and run-picking are the foraging methods adopted. In Europe, for example, flycatching by Grey Wagtails is much less common than picking during the winter months. Although all wagtail species will forage by flycatching, this technique is correlated with tail length, and is practised more frequently by the longer-tailed species than it is by the shorter-tailed ones. This is evident, for example, in western Europe, where Grey Wagtails adopt

*The **Rock Pipit** is the only species of motacillid restricted to Europe. The bird seen here is foraging in its classic tideline niche, surrounded by drifts of wrack and stems of kelp. An in-depth study in Cornwall, south-west England, determined that the winter diet of this bird consisted largely of molluscs such as periwinkles* (Littorina), *chironomid larvae, kelp fly larvae, and various isopod crustaceans such as sea slaters, sandhoppers and crabs. The Rock Pipit is even known to catch and eat small fish, for example sandeels* (Ammodytes), *which it beats against a rock then swallows head-first.*

[*Anthus petrosus petrosus*, Ouessant Island, France. Photo: Rafael Armada]

In a detailed study of foraging habits in the ***Australasian Pipit*** *the gizzards of 57 birds were examined. Of these, the vast majority (80%) had consumed almost exclusively invertebrates (at least 90% by dry-weight of contents). This individual has captured a large orthopteran, a favourite prey-item according to the aforementioned research: grasshoppers or crickets of some description were present in 18% of the gizzards studied. The most popular items, however, were beetles, hymenoptera (mostly ants) and dipteran flies; these were present in 77%, 67% and 63% of gizzards, respectively. In addition, small numbers of molluscs, including an aquatic snail, and crustacean, including small crabs, were noted in the diet. The remainder of consumed food was usually made up of seeds taken from a wide variety of plants.*

[*Anthus novaeseelandiae*, Goomboorian, Gympie, Queensland, Australia. Photo: ANT/NHPA]

The range of invertebrates recorded in the diet of the ***Tree Pipit*** *is truly impressive, spanning from spiders, beetles and earwigs to lacewings, termites, millipedes and grasshoppers. It is also known to eat snails, and the vegetable portion of its diet includes fruit and buds, seeds and grains, and even nectar of* Erythrina *flowers on its wintering grounds. For a bird with such a fine bill it is therefore something of a generalist. Despite this variable food supply, one item exerts more influence on the life-cycle than any other: the caterpillar. The Tree Pipit is a migratory bird, returning to temperate heathlands and woodland edges in the spring, and timing the onset of breeding to coincide with the flush of caterpillars and other soft-bodied insects in these habitats. Under normal circumstances, a Tree Pipit will swallow caterpillars one at a time, but when there is a hungry brood to feed, a whole beakful is required.*

[*Anthus trivialis trivialis*, Capel Cynon, Llandysul, Wales. Photo: Melvin Grey/NHPA]

*In general, longclaws feed in a similar fashion to pipits, and target similar prey. The **Cape Longclaw** usually picks food from the ground, but it has been seen performing repeated aerial sallies after flying prey, usually alate termites swarming upwards, after rain. Unlike pipits and wagtails, it even uses its robust legs to scratch at termite mounds, opening tunnels and extracting prey items from within. Orthopterans and coleopterans are its favourite food, and indeed they seem to make up around two-thirds of the diet of most large terrestrial grassland motacillids.*

[*Macronyx capensis*, South Africa. Photo: David Hosking/ FLPA]

flycatching as a foraging strategy much more frequently than do the comparatively short-tailed Yellow Wagtails, while White Wagtails are intermediate in this respect.

Pipits and longclaws are mainly terrestrial feeders and have a more restricted range of foraging techniques than do the wagtails. Nevertheless, they do occasionally fly up into the air for a short distance in order to grab a flying insect. One notable record, in England, was of a flock of 50 Meadow Pipits all of which were flycatching in sunny weather at a sewage farm in Surrey. When winged termites are emerging, however, as in the Afrotropics, all motacillids will try to catch these, either in the air or on the ground, and almost invariably accompanied by a wide variety of other avian species.

Hovering demands much expenditure of energy, and it is not a strategy commonly used by members of this family. Individuals occasionally hover briefly in order to snatch an insect from tall vegetation or rocks, but there are several records of more persistent hovering. In one case, a female Grey Wagtail in Ireland was observed as it collected insects from tree trunks. The bird hovered about 1 m above the ground in front of one tree, moving around it while still hovering, and every few seconds moving closer and picking insects from the bark. It repeated this at another tree, before carrying off the insects to its nestlings. Similar persistent hovering was noted for a White Wagtail, which hovered 10 cm above the ground while it snapped up small winged insects just above a patch of tall grass. Such bouts lasted for half a minute at a time. Yellow Wagtails occasionally hover over grass or around cattle in order to pick off insects.

Foraging strategies vary from one species to another, and the strategy adopted by any species will depend very much on the habitat and on the availability of potential prey. For example, in open grassland or at the muddy edges of pools where there is much terrestrial prey, picking is the most frequent strategy. By rivers where there are at times many winged insects, flycatching can be important. A study in the UK showed that, when Yellow Wagtails were feeding at shallow pools, picking was the method used almost exclusively; when feeding around cow pats, on the other hand, picking was still the main method used, but darting and flycatching were also important, together representing over 16% of observations. An intriguing observation was made in New Guinea, where wintering Yellow Wagtails were seen to spin around in tight circles, but it is not known if this is a feeding tactic.

The season of the year and the ambient temperature, because they affect the availability of winged insects, also determine the method of foraging. During the winter months, when many insects have larval or nymphal stages, or during periods when small insects are grounded because of wet and cold weather, motacillids pick prey items from the ground. When temperatures rise and, for example, small midges become active, run-picking and jumping are employed more. Hovering or vegetation-gleaning may be adopted when a mass emergence of damselflies takes place from nymphs that have crawled up vegetation on a riverbank. In warm sunny weather, as in the northern spring and summer, when numerous mayflies and caddis flies are on the wing, it becomes more profitable for Grey Wagtails to hunt these by using aerial flycatching from a perch. Most motacillids are very adaptable and can quickly switch from one foraging strategy to another, more profitable one.

Foraging locations can also change according to season and weather. In the Czech Republic, it was found that the foraging location of Grey Wagtails changed both with weather conditions and with the height of the water in the river. In dull weather, the wagtails exploited mainly the area around the river edge, picking prey from above and just below the water's surface. They also foraged by picking in riparian vegetation. When water levels rose after a storm, and at times of low insect activity, the wagtails temporarily exploited such places as piles of flood debris, dead branches, wet ground and manure. This ability to switch to different prey and quickly to change foraging strategy and locations is exhibited by many other members of the family, the Water Pipit being just one example. In Africa, many pipits and longclaws often appear very quickly at recently burnt ground, where prey is presumably more visible. Grassveld and Bush Pipits and Cape Longclaws forage on grassland within an hour of its being burnt or on the following day. Rock Pipits, too, change their foraging locations between seasons and in accordance with temperatures. A study of this species in south-west England revealed that, in the summer, the Rock Pipits fed in vegetation above the cliffs, where insects were more active, whereas in the winter they foraged along the shore; moreover, they were also found on the shore

*The **White Wagtail** has the habit of walking in water in pursuit of aquatic larvae and nymphs. This individual has snatched just such an item from the surface of a puddle, but wagtails hunting in wetlands are by no means restricted to insect prey. The British race of this species was once watched catching the fry of a perch* (Perca fluviatilis) *to feed to its offspring. Indeed, on one visit it managed to carry three of these fry crossways in its bill, as if auditioning to be a puffin* (Fratercula)*!*

[*Motacilla alba leucopsis*, Long Valley, Hong Kong. Photo: Martin Hale]

on cool summer mornings and, conversely, they moved to the cliff tops to forage inland on mild winter days.

Seasonal changes in foraging location are well demonstrated by the Grey Wagtail. In the breeding season, this well-studied species shows a preference for feeding by upland rivers in the vicinity of riffles, or where broadleaf woodland borders the riverbanks. The insect communities in riffles, areas where fast-flowing shallow water runs over rocks or pebbles, are dominated by chironomid midges, blackflies, mayflies and caddis flies. Riffles are, therefore, rich feeding areas. Likewise, insects falling from trees into rivers provide abundant and often large prey, such as caterpillars. In the winter months, Grey Wagtails forage in a wider variety of habitats, and often away from upland rivers and streams. They then visit farmyards and dung heaps or slurry pits, ponds, sewage works, watercress beds, gardens and parks in towns, and lowland rivers. The visits made to Liverpool city centre by a maggot-eating Grey Wagtail, mentioned above, took place in the winter months, when insects are scarce.

Several other species, notably long-distance or altitudinal migrants, also switch habitats in the winter. Water Pipits, for example, descend from mountain pastures to lowland habitats, including watercress beds, and Meadow Pipits move from upland moorland to lowland pastures, coastal habitats and sewage works.

Even individuals of the same species, foraging in the same location, may exploit different niches. In Nigeria, wintering Yellow Wagtails were found to use four types of foraging niche. Most of them foraged in association with cattle, some 80% of the local population using this niche during the dry season. Fewer than 20% set up territories along streams, the males being territorial through the dry season. About 10% of the wagtails foraged in cultivated areas. Other habitats in grassland were utilized after rain, or wetter areas of it exploited intermittently. In the winter months, some White Wagtails may display territorial behaviour and defend small piles of food. If food is more evenly spaced, then they feed in flocks.

Where two or more motacillids share a habitat, differences in foraging behaviour, including both technique and location, as well as differences in choice of prey, may help to segregate them. The species' size and the length and width of its bill also influence the size of prey taken. The long tail of the Grey and Mountain Wagtails enables these species to balance on rocks in torrential streams and to reach over and catch prey on the rocks at or below the water surface; White Wagtails tend to overbalance if they try this technique. In Japan, studies of White and Japanese Wagtails on a river during the winter showed that the two species had similar feeding techniques, spending most time in picking on the ground. Compared with Japanese Wagtails, however, White Wagtails did more flycatching and foraged in drier areas, often well away from the river. A Swiss study revealed that Grey Wagtails spent 50% of their foraging time within the river corridor, and a further 18% and 13%, respectively, on paths and in meadows. White Wagtails using the same area also foraged along the river, but they fed predominantly in meadows and on paths, and also in sedges. In a further example, from a study undertaken near Oxford, in England, Yellow Wagtails relied heavily on picking, as opposed to run-picking and flycatching, whereas White Wagtails in the same habitat used the picking technique less frequently and both run-picking and flycatching more so.

In parts of Africa, migrant territorial Yellow Wagtails are potentially in competition with Plain-backed and Red-throated Pipits. The Plain-backed Pipits are larger and heavier, but rather few in number, and their impact therefore is probably small, although an individual does displace any Yellow Wagtail that it encounters. The smaller-bodied and smaller-billed Red-throated Pipit gives way to Yellow Wagtails, but it occurs in large numbers in the same habitat. It has been suggested that both pipits have a more limited range of feeding techniques compared with Yellow Wagtails. The pipits peck and fly close to the ground, and so they probably have a more restricted diet than does the more versatile Yellow Wagtail.

Pipits, longclaws and wagtails are sometimes robbed of their food by larger species of bird. In the Afrotropics, for example, there is a record of a Fork-tailed Drongo (*Dicrurus adsimilis*) diving at a Cape Longclaw in an attempt to steal its food, and it is reported that Fiscal Shrikes (*Lanius collaris*) frequently kleptoparasitize these longclaws both in rank grassland and in burnt or mown grassland. On the other hand, wagtails may occasionally kleptoparasitize other birds. In Britain, a White Wagtail of the local race *yarrellii* was observed as it harassed a Northern House Martin (*Delichon urbicum*), so much so that the martin presented the wagtail with a foodball, expelled from its own mouth.

It seems probable that the majority of motacillids obtain sufficient water from the normal diet that they do not need to drink. In very arid areas in Botswana, however, both the Grassveld Pipit and the Buffy Pipit have been observed to drink at a small pool.

Breeding

Although a few species have been studied in detail, rather little is known of the breeding habits of many motacillids, especially those in South America and in Africa. Data are virtually or entirely lacking for such species as the Long-legged Pipit and the newly described Long-tailed Pipit. For those motacillids for which sufficient information is available, it seems that the courtship displays and the type of nest built vary only little among the species.

Monogamy is the standard breeding system among the pipits, longclaws and wagtails, but a small proportion of individuals of some species may be polygynous or polyandrous. In a study of the Water Pipit, K. Bollmann found that, of 278 social mating groups, 86% were monogamous; of the remainder, 9% referred to bachelors, 3% to polygyny and 2% to polyandry. He concluded that age was the most reliable criterion for mate choice and that monogamy can be expected to be the dominant system, especially when both parents are required to incubate the eggs and to feed and rear the young. Polygyny occurs rarely among Meadow and Tree Pipits, but a 32% incidence of polygyny was found among Rock Pipits and a 6·7% incidence among Tawny Pipits. It is possible that, as more detailed studies of the mating systems of other species of motacillid are carried out, polygyny or polyandry may be found to be widespread, if occasional, among the members of this family.

Timing of breeding is correlated with periods of peak insect activity and vegetation cover. Across the northern and central parts of the Northern Hemisphere, motacillids invariably breed in the spring. In the Afrotropics, many breed during or just after rains, when there is good ground cover to conceal nests and an abundant supply of insect food. A few species, such as the Cape Wagtail in southern Africa, may breed at any time of the year and more or less continuously throughout it. African Pied Wagtails breed for six months of the year in Malawi, starting before the rains and continuing through them, with peaks of laying in March and October. In Zimbabwe they breed in all months except May and January, but breeding activity reaches a peak from August to October, before the rains.

For a given species, the timing of breeding may vary from year to year, with egg-laying starting earlier in mild springs and later in cold weather. In a study of the British subspecies *yarrellii* of the White Wagtail, it was shown that April temperatures affected the timing of laying. On average, a 1°C rise in mean April temperatures led to a 7% increase in the proportion of clutches started in April; a temperature increase of 1°C brought forward the mean first-egg date by about two days. Moreover, there is some evidence that Grey Wagtails in Wales have gradually been laying earlier over the period from the 1980s to the late 1990s, with more clutches now being started in March or early April than was previously the case.

In the Palearctic Region, breeding occurs earlier, and continues for longer, in the south and west of a species' range, and takes place later at high latitudes farther north. Meadow Pipits, for example, nest from early April until August in central and western Europe, whereas in Swedish Lapland they lay only from mid-June until early July. Likewise, Citrine Wagtails in southern Russia lay from late April, whereas in the north of the country laying starts in mid-June. Similarly, Red-throated Pipits begin egg-laying at the end of May in the south of their range, but not until mid-June or even July in the north. A mass of information has been gathered on the breeding behaviour of Grey Wagtails, enabling a fairy comprehensive picture to be presented. The breeding season of this species begins a month earlier in southern Europe than in Sweden, while Grey Wagtails in Ireland breed earlier than those in Britain. Further, laying normally begins later at higher elevations. In the Swiss Alps, Grey Wagtails laid on average 12·7 days later for each 100-m increase in altitude. The birds had to wait until the snow had melted before returning to their high-altitude territories. The lowest-lying territories in the Alps were occupied in mid-March, those between 1100 m and 1200 m by mid-April and the highest ones, those up to 1300 m, not until the middle of May. Grey Wagtails in Germany laid two days later for each 50-m increase in altitude. Meadow and Berthelot's Pipits are just two examples of other species that lay later at higher elevations.

All motacillids for which sufficient information is available establish breeding territories. Although the Citrine Wagtail may

*The **Cape Wagtail** spends most of its time in classic wagtail fashion, darting around pastures, beaches, lawns and cultivation, and very often beside water, in fact virtually anywhere where there are small insects to be snatched from the ground or surrounding air. In some regions of South Africa it has become so tame that it enters houses and feeds on the kitchen floor for crumbs. Along with several other wagtails it will make short aerial sallies from higher perches, or longer fluttering pursuits of airborne prey in the manner of flycatching birds. In this instance, it has caught a damselfly. With insects of this type, wagtails normally knock off the wings before swallowing the body.*

[*Motacilla capensis capensis*, South Africa. Photo: HPH Photography/ Bruce Coleman]

Wagtails living on fast-running streams tend to forage by picking at the water or rocks for insects. They run about quickly, or walk, wagging their tails conspicuously, and they will also fly up a short distance to catch insects in flight. This ***Grey Wagtail*** *reveals its adroit foraging technique, and its penchant for aquatic larvae, by snatching one from rushing water. In fact, so keen is this species on wriggly prey, especially in winter, that one bird entered a fishing-tackle shop in Liverpool and collected maggots from a tray. In summer, adult dipteran flies were found to form an important part of the diet of this species in Wales, contributing 55-64% of items taken by adults. Similar results were obtained at other European sites.*

[*Motacilla cinerea cinerea*, Osona, Catalonia, Spain. Photo: David Vilasís]

nest semi-colonially, individual pairs are still strongly territorial. Territories of open-country species are roughly circular, but those of coastal and riverine species are linear. The territory of a Meadow Pipit includes the extremes of its foraging area around the nest, but within this it has a core area that it uses, and within this core area it has a normal living area.

Breeding African Pied Wagtails were found to have territory sizes of about 100 ha, but this is very large compared with the sizes recorded for many other motacillids. In the Austrian Alps, Water Pipits occur at densities of 0·8-1·8 territories per 10 ha, with 3·6 territories/10 ha recorded along the timber-line. Breeding densities of Tree and Meadow Pipits can reach 60 or 70 pairs/km^2, and occasionally more, in favoured habitats. Figures of 100 pairs/km^2 and 126 pairs/km^2 have been recorded for Tree Pipits in a German vineyard and on Swiss traditional farmland, respectively, and even higher estimates have been reported for Meadow Pipits, including 300 pairs/km^2 on water meadows in the former USSR and a staggering 964 pairs/km^2 on short grassland in Germany. Elsewhere, 1 km^2 of short tussocky grassland on the Kinangop Plateau, in Kenya, can hold up to 40 adult Sharpe's Longclaws, corresponding to 20 pairs, the mean home range of a pair being only 0·5 ha. Cape Wagtails are very common throughout much of their range, especially in southern South Africa, and farther north, at Sandwich Harbour, in Namibia, a few hundred pairs were concentrated in a small area around freshwater pools.

Riverine wagtails, as already stated, have linear territories. In Britain, there can be 20-40 pairs of Grey Wagtails along 10 km of upland river, and on rich wooded upland streams with steep gradients the distance between pairs can be no more than 200-300 m. In Germany and Switzerland, mean densities per kilometre of river of, respectively, 0·94-1·74 pairs and 1·26 pairs were recorded. In the Swiss Alps, however, the figure was 2·8 pairs on streams at the highest altitudes, where White-breasted Dippers (*Cinclus cinclus*) were absent. Elsewhere in Europe, observers have recorded territory lengths for Grey Wagtail pairs of: 250-450 m, occasionally more than 600 m, in the Czech Republic; 900 m in Denmark; and 520-775 m in different parts of Switzerland. In Germany, some Grey Wagtails had territories extending up to 2600 m, and on modified and polluted streams very low densities of just 0·01-0·05 pairs/km were found. In Japan, territory length is 300-500 m. Mountain Wagtails in Ethiopia and South Africa generally breed at densities of 10-25 pairs/10 km, and territory length can be as little as 400 m.

Among the very few truly coastal species, the Rock Pipit is the only one for which adequate information is available. Along the shores of north-west Europe, there can be densities of 3-5 pairs of Rock Pipits for every kilometre of suitable coastline.

Some wagtails are very aggressive when breeding, defending the territory not only from conspecifics but also from other species. White Wagtails, for example, will chase off Grey Wagtails or Japanese Wagtails that are nesting nearby, and Grey Wagtails sometimes pursue dippers. White Wagtails in Britain have also been recorded as chasing Common Ringed Plovers (*Charadrius hiaticula*) from the breeding territory, and African Pied Wagtails sometimes drive off Common Sandpipers (*Actitis hypoleucos*), although the latter are only non-breeding visitors to that continent.

Many motacillids have a courtship display-flight in which the male flies into the air and then descends, while singing, with vibrating raised wings and tail. The nature of this display-flight and the accompanying song are useful aids in the identification of pipits. Sprague's Pipit in North America has one of the most spectacular aerial flights, reaching 150 m or more above the ground. Some other species, such as the Yellowish and Ochre-breasted Pipits in South America, ascend to no more than 10-25 m. Another Neotropical species, the Correndera Pipit, rises to 40 m, and then hovers, or glides down almost to the ground, before climbing again, singing as it hovers or descends. Others, such as the Malindi Pipit in East Africa, normally sing from a perch, a small tree, a fence post or a termite mound, but some may fly out or down from the tree, singing as they descend. The Grey Wagtail has a wonderful parachuting display-flight: from a tree or overhead wire, the male descends, with the wings lowered and spread, the tail depressed and the yellow rump feathers conspicuously puffed up, singing all the while until it reaches the ground. The Tree and Olive-backed Pipits perform a similar parachute display, beginning from a perch in a tree. In contrast, the Short-tailed Pipit displays on the ground, with rapidly flicked wings, or flies a few metres above the ground in wide circles while giving nasal calls and buzzing wing-snaps.

Greeting displays are simple. Typically, the male, with his wings outspread and quivering, approaches the female. When the male

*This **Yellow Wagtail** is demonstrating a widespread habit of many pipits, longclaws and wagtails. When foraging, they often associate with grazing livestock, reaping the benefit of increased foraging success. Their hit-rate is likely to be higher for two good reasons. First, insects are attracted to livestock and commoner in their vicinity. Second, large mammals tend to disturb cryptic insects when they walk, making them easier for wagtails to spot. In this case the "beaters" are sheep, but more often than not they are cattle, and in the winter quarters it might just as well be herds of wild ungulates.*

[*Motacilla flava flava*, Lesbos, Greece. Photo: David Tipling/ Windrush]

White Wagtail arrives in the pair's territory, the female greets him by holding her tail and head raised at an angle of 45 degrees. She sometimes adopts a cringing posture, and quivers her wings in solicitation. Aggressive displays, often with the body plumage puffed up and the tail raised, are directed towards intruders.

Displays continue during the breeding cycle, the male displaying to the female at change-overs during the incubation stage. An interesting observation at the nest of a pair of Madagascar Wagtails may serve as an example. When the male delivered food to the brooding female, the latter left the nest and perched beside her mate; he proceeded to give a display during which he cocked his tail almost vertically and fluttered his closed wings rapidly, and then spread the wings slightly while shaking the body and singing.

All pipits and longclaws and most species of wagtail almost invariably build their nests on the ground, often in a hollow or

*While most food is taken from the ground, or in short aerial sallies, a variable proportion is taken from foliage. This **Yellow Wagtail** is probably searching for caterpillars and the like, hidden in the leaves of a flowering shrub. As well as insects, bushes sometimes provide a few berries or other plant matter, such as tiny buds. The plumage of this particular bird suggests a complex genealogical history. With its black head and bicoloured supercilium, it appears to be somewhat intermediate between "*superciliaris*" (itself an intergrade between* feldegg *and* flava*) and "*xanthophrys*" (an intergrade between* feldegg *and* lutea*). In many cases, the direct parentage of Yellow Wagtails cannot be deciphered.*

[*Motacilla flava*, Lesbos, Greece. Photo: Richard Brooks/ FLPA]

Wagtails, such as the ***Yellow Wagtail****, are capable of capturing highly manoeuvrable aerial prey. In most cases they are caught during "run-picks", which equates to a darting run towards a sitting insect, followed by an attempt to snatch it with the bill. If the insect is slow, it may be caught before it tries to escape. More usually, it takes to the air and the wagtail is forced to follow suit. A brief but agile fluttering sally into the air usually suffices, and if the insect is not caught in the first metre or so, the wagtail rarely prolongs its pursuit. Only slow-flying insects, such as alate termites and certain moths, are habitually chased in level flight.*

[*Motacilla flava iberiae*, Cantalpino, Salamanca, Spain. Photo: Francisco Martín Martín]

Field studies in temperate latitudes suggest that motacillids rarely drink, but in semi-arid tropical regions this rule does not hold. Moreover, wagtails and pipits often visit oases, saltpans and sewage farms in North Africa and the Middle East during migration periods. After a long, tiring flight, this ***Red-throated Pipit*** *is thirsty. It drinks in the manner common to all passerines, holding a draught of liquid in the bill, then letting it trickle down the throat by tilting the head.*

[*Anthus cervinus*. Photo: G. K. Brown/Ardea]

other depression, such as a footprint. The hollow may be excavated by the female, as in the case of Tree Pipits, or by the male, as occurs among Red-throated Pipits. The nest itself is generally built in or under vegetation, or close to a tussock, or under a rock. In a study in Germany, it was found that Meadow Pipits preferred sloping ground to flat ground, with 81% of nests being on slopes and ditchbanks; over 95% of nests were in depressions and more than 92% under sheltering vegetation. Nests of some species, such as Yellow Wagtails and Richard's and Red-throated Pipits, are sometimes at the end of short runs or tunnels through grass.

Few motacillids nest on or in trees, but the Forest Wagtail is a notable exception. This aberrant Asian wagtail always builds its nests on branches in trees, making a neat cup, the outside of which is covered with lichens. The nest is therefore well camouflaged against the lichen-covered branches. Trees are sometimes used, normally on an irregular basis, by a small number of other species. Grey Wagtails occasionally nest in trees in Europe, as, for example, in Wales, where pairs have built in the epicormic growth of lime trees (*Tilia*) and, less often, in forks of trees or on stumps, upturned tree roots being a more frequent site. In the Azores, however, tree nests are commonplace among the Grey Wagtails of the local subspecies *patriciae*. Yellow Wagtails have been known to build in willow stumps and in the forked branches of a thorn hedge, and Cape Wagtails often nest in bushes and sometimes in trees. As long ago as the 1960s, Winterbottom referred to 51 records of Cape Wagtail nests placed in or under bushes and 16 in trees in the Western Cape of South Africa, and twelve nests were found in trees in the north-east of that country. In areas liable to flooding, the Yellow-throated Longclaw may build its nest up to 15 cm above the ground on a tussock, with an approach ramp, and one pair was recorded as nesting 60 cm above the ground in an acacia bush (*Acacia*).

Crevices in banks and cliffs are used by Rock and Water Pipits and by Grey and Mountain Wagtails, and holes or ledges in buildings, walls and in or under bridges are common nest-sites for Grey, Mountain, White, African Pied and Cape Wagtails. Indeed, many Grey Wagtail nests are associated with artificial structures. For example, in Wales, where this species has received intensive study, more than 75% of nests were in or under bridges, in walls, or associated with buildings, weirs, dams or flood-protection works; on some Welsh rivers, almost all nests located were in such situations. Likewise, 80% of this species' nests in the Swiss Alps were in or on buildings, dams, walls, bridges and nestboxes, and on mountain rivers in the Czech Republic 81% of nest-sites were below bridges or associated with walls of weirs, with a further 11·4% in buildings. In Ireland, too, as many as 97% of nests were in or on artificial structures, mainly bridges. The White Wagtail displays a similar, if less developed, liking for artificial structures. Thus, half of the nest record cards for the British subspecies *yarrellii* referred to sites associated with buildings or other structures. These nests were usually in holes or crevices or on ledges of walls, bridges, locks or buildings, and most were up to 1·5 m from the ground, with 24% between 1·5 m and 3 m and the highest at 15·2 m. Only 9% were on the ground, compared with 96% of Yellow Wagtail nests.

Wagtails will often make use of the nest of another species. Grey Wagtails in Wales, for instance, frequently constructed their nest within or on top of an old domed nest of a White-throated Dipper, and also used the riverbank burrows of Collared Sand Martins (*Riparia riparia*), and almost 8% of 220 Grey Wagtail nests in Ireland were in or on dipper nests. Similarly, White Wagtails will also exploit nests of other species, notably those of Eurasian Blackbirds (*Turdus merula*), and they are known to use the holes of kingfishers, Collared Sand Martins and Common Redstarts (*Phoenicurus phoenicurus*) as breeding sites.

The typical motacillid nest is a deep grass cup lined with finer material, and usually concealed in vegetation, often at the base of a tussock, or hidden in a crevice. Dry grass is the favoured material, with varying amounts of moss, rootlets and leaves added. The nest of the Paddyfield Pipit may be partially domed, and that of the White-browed Wagtail can be quite a substantial structure. The Forest Wagtail, the only member of the family that regularly nests in trees, constructs a compact, firm cup of twigs, leaves, fine grasses and rootlets, all held together with moss and cobwebs, and draped with lichen to match its surroundings. The lining is of horsehair, wool, fur or moss roots.

From the limited information available, it appears that the precise site for the nest is chosen by the female, as has been found to be the case with both the Meadow Pipit and the Yellow Wagtail.

Nothing is known about the roles played by the sexes of the Mekong Wagtail in nest-building. For all other wagtails, however, it appears that both sexes take part in the collecting of nest mate-

rial and the building of the nest. The amount of work contributed by each sex varies from one species to another. In the case of the Yellow Wagtail, it is mainly the female that carries out the work, and it is reported that the nest of the Citrine Wagtail is built by the female. The female Forest Wagtail is accompanied by her mate in the nest-construction process, but she builds the nest entirely on her own, with no assistance from the male. Nevertheless, variation is evident among different pairs of a species. The male White Wagtail may build the whole nest on his own or he may build part of it; often, he starts the nest and the female finishes it. Various studies of the Grey Wagtail have revealed that both sexes collect grass and moss, and both incorporate this material into the nest. At one site in Wales, the female carried 46 beakfuls of material to the nest in one hour, compared with the male's 17 beakfuls.

Among the pipits, the male often accompanies the female as she builds, or he brings material to her and she incorporates this into the nest. Thus, the female Berthelot's Pipit builds the nest. In the case of the Red-throated Pipit, the male starts the nest, creating a hollow in moss, but the female then carries out the building work, using material brought in by both herself and her mate and, in the latter stages, by her mate alone. Similarly, the male Water Pipit collects material but it is the female that constructs the nest. Few data exist for longclaws, but observations indicate that the females of the Rosy-breasted and Grimwood's Longclaws build, with the males in attendance.

When a second brood is to be raised, the pair either will simply renovate and reline the nest or will build a new one as soon as young from the first brood fledge. Reuse of nest-sites is probably rare among ground-nesting species, but Grey Wagtails frequently reuse nests in walls or under bridges. One nest in the New Forest, in southern England, was used for three consecutive broods in one season. The Cape Wagtail, too, sometimes reuses its nest for a second brood, and there is one record of the same nest being used six times.

The eggs of most motacillids are generally buffy or creamy, sometimes greenish, with dark brown or reddish-brown mottles or speckling. Clutch size ranges from three to seven eggs, but is usually 4-6 in temperate regions. It is lower in the tropics, where a clutch of 2-3 eggs is normal. Bird species in the Northern Hemisphere often lay larger clutches at higher latitudes, where the longer days in summer enable them to forage for longer periods and, consequently, to raise larger broods. In North America, for example, Buff-bellied Pipits breeding at latitudes between 35° and 45° N have a mean clutch size of 4·7 eggs, whereas the figure for those at 65°-75° N is 5·5. Similarly, the mean clutch size of Meadow Pipits in Europe ranged from 4·6 eggs in Germany to 5·4 in south Norway and 5·7 in north Norway, and that of Grey Wagtails was about 5 in Wales, 5·2 in Scotland, about 5·3 in Germany, the Czech Republic and Switzerland, 5·5 in Denmark and 5·8 in Sweden. Grey Wagtails in Ireland laid smaller clutches than those in England and Wales.

For the Yellow Wagtail, various studies demonstrated an increase in clutch size by one egg for each 19° of latitude throughout Europe. At any given latitude, however, larger clutches were laid in western Europe than in eastern Europe. There was evidence for a reversed latitudinal cline also in eastern Asia, where clutch size is smaller at higher latitudes and smaller than at equivalent latitudes in Europe. C. P. Bell postulated that Yellow Wagtail populations that spend the non-breeding season in East Africa and South-east Asia laid smaller clutches than did those wintering in West Africa and India. He thought that this was because higher winter mortality among the latter populations could reduce breeding density, thereby leading to less competition for resources and allowing the production of larger clutches. Within Britain, one observer found little evidence for an effect of latitude or altitude on clutch size of Meadow Pipits, although another researcher found that average clutch size decreased with altitude, from 4·5 eggs near sea-level to less than 4·1 eggs above 333 m. Clutch size is also influenced by the availability of food before the start of laying.

Clutch sizes sometimes decline through the season, as has been found in some studies of White Wagtails. More commonly, however, they increase until the early or middle part of the summer, and decrease thereafter. Five is the most frequent clutch size for first-brood Tree Pipits, whereas four is the most frequent size of second clutches. In Wales, Grey Wagtail clutches laid in May were larger than those in April or June. Some observers have noted that second clutches of this species are larger than first clutches, which is not at odds with the Welsh results, but in the Czech Republic a steady decline in clutch size occurred as the season progressed. Differences in food availability through the season at different localities may help to explain these contrasting results.

Like the larks (Alaudidae), many pipits, wagtails and longclaws perform flight displays. This shared tendency is presumably an adaptation to open-country environments where prominent perches are in short supply. Some pipits attain great heights during song flights, and may sing continuously for up to an hour in flight. The display of the ***Red-throated Pipit*** *is typical of the smaller* Anthus *species: it rises obliquely, on fluttering wings, till it reaches a height of about 20 m, then it parachutes down with wings uplifted, singing loudly, until it plummets the last few metres to earth, whereupon it falls silent. A variant involves a more level fluttering song flight, sometimes over a distance of some 50 m, before the bird drops down.*

[*Anthus cervinus*, Lapland, Finland. Photo: Tomi Muukkonen]

*The "true" wagtails regularly enact distinctive displays. In the **African Pied Wagtail**, one individual often bends forward, cocking the tail almost vertically and shuffling the wings. Another individual may stand tall, with tail held low and bill tilted skywards. The general pattern of displays seems relatively constant across the genus. Their function, however, is unclear; they may work as an appeasement display between rivals, or a pre-copulatory ritual, and they sometimes occur between pair-members as a greeting near the nest.*

[*Motacilla aguimp*, Kruger National Park, South Africa. Photos: Patricio Robles Gil/ Sierra Madre]

Very occasionally, nests have been found to contain an exceptionally large number of eggs, but this is probably the result of two females laying in the same nest. This was the case with a Grey Wagtail nest that held eleven eggs.

Among those species for which data are available, laying takes place early in the morning, at daily intervals. Incubation begins with the last egg in the case of the Tawny Pipit and the Yellow and Grey Wagtails. Water Pipits and sometimes Meadow Pipits, however, start to incubate when the penultimate egg is laid. With Olive-backed and Red-throated Pipits, incubation may start after the second or third egg; hatching is then asynchronous, spread over two days. In addition, a Grey Wagtail has sometimes been seen to roost on the nest before the clutch is complete, and there is one record of this species starting to incubate before the full clutch had been laid.

The incubation period is usually 11-14 days, occasionally a day or two longer. It may be shorter as the season progresses. For all species of wagtail that have been studied, both the male and the female incubate the eggs, although in many cases the female takes the larger share, may sit for longer periods and usually incubates at night. Observations made on the Grey Wagtail reveal that the eggs are only rarely left unattended; each sex sits for bouts of 20-90 minutes, the female often for the longer periods. Female Yellow Wagtails incubate for 67% of the time and males only 17%, the nest being unattended during the rest of the time. Change-overs at the nest are unobtrusive. The sitting bird slips off quietly, calling only when some distance away. Its mate then approaches, carefully and slowly, frequently halting to look around, and then flies quietly to the nest.

Observations at nests of the Forest Wagtail indicate that incubation is by the female alone. Among pipits, too, incubation is reputedly carried out by the female in the case of the Buff-bellied, Sprague's, Red-throated, Tree and Water Pipits. The male brings food to his incubating partner. In observations of breeding Water Pipits, the female has been found to incubate for an average of 45 minutes per hour, and to spend the rest in perching or foraging away from the nest. In severe weather she spends less time away from the nest, but when food became scarce the females had to spend more time in foraging and less in incubating. There are few data on the roles of the sexes among longclaws, but it is reported that the females of the Yellow-throated and Rosy-breasted Longclaws undertake all or most of the incubation.

Once the eggs have hatched, the chicks are closely brooded by both parents. The female usually takes a larger share in the brooding of small young, and it appears that she alone broods at night. The female's stints also tend to be longer than those of the male. In all motacillids studied, both parents feed the chicks and both also remove faecal sacs. In the early stages, the sacs are removed directly from the young chicks and then swallowed. Later, they are taken from the edge of the nest and dropped some distance away; riverine species often drop the sacs into the water near the nest. The nestling period, from the time of hatching to the time when the young leave the nest, is generally 11-14 days, but sometimes, as in the case of the Mountain Wagtail, up to 16 or 17 days. Calculation of an exact period is complicated by the fact that some chicks of ground-nesting species may leave the nest prematurely if they are disturbed.

Normally, for almost all motacillid species studied, both sexes accompany the juveniles for two or more weeks, and sometimes up to eight weeks. It has been reported that, at least occasionally, the female Cape Wagtail alone cares for the juveniles, for 20-25 days. When a second brood is to be attempted, and the female lays again soon after the first brood has left the nest, one of the adults then cares for the fledged young while the other is incubating. Among those species in which only the female incubates, the male will look after the needs of the juveniles while his partner incubates the next clutch. The parents will often tolerate the nearby presence of their offspring for nearly nine weeks, although final broods of the season are tolerated for longer periods than are earlier ones. Once they reach independence, the siblings of a brood often remain together as a group for months after fledging, even migrating together.

Species nesting at high latitudes or at high elevations, where the breeding season is short, are single-brooded. Elsewhere, they usually rear two and occasionally three broods in a season. In tropical and subtropical regions, some motacillids, such as the African Pied and Cape Wagtails, may breed almost continuously through the year. Cape Wagtails can raise four to six broods in a single season, and one pair had eight nests and laid 24 or 25 eggs between September 1947 and August 1948, while another laid 50 eggs in 15 clutches over 48 months, rearing 29 fledglings. Intervals between broods vary greatly, and can be up to three weeks, but generally a few days to one or two weeks may elapse between the fledging of one brood and the laying of the next clutch. White Wagtails in Britain were found to have an average interval of 12 days between the two events. In one case, when a Grey Wagtail pair produced three successful broods, there was only one day between the fledging of the second brood and the commencement of the third.

Occasionally, the presence of helpers at the nest has been recorded. In one instance, a Cape Wagtail, possibly a youngster from an earlier brood, took turns with the breeding adults in the

All motacillids are essentially monogamous and territorial. They build a shallow cup of coarse dry grass, lined with rootlets, fibre and hair. This structure is usually placed in a depression, often concealed under a tussock, a rock or the edge of a small shrub. This ***Grassveld Pipit*** *is probably a female, given that males of most motacillids contribute very little to the actual nest building. They do tend to accompany the female throughout this period, although this has little to do with companionship and assistance, and a lot to do with mate-guarding and the evolutionary influence of sperm competition.*

incubation of the eggs. Similarly, a juvenile Madagascar Wagtail assisted its parents in the rearing of a second brood; as soon as the second clutch hatched, the juvenile joined its parents in feeding the nestlings. There is also a record of nestling Meadow Pipits being fed by a juvenile Meadow Pipit that was unrelated to the adult nest-owners.

When adults are feeding their young, they are sometimes stimulated to feed chicks of other species. There are several records of Grey Wagtails feeding dipper chicks. One such case involved a pair of these wagtails that fed both its own nestlings and those in a nearby White-throated Dipper nest over an eight-day period; the calls and begging behaviour of the dipper nestlings may have elicited this response. Likewise, a Tree Pipit was observed to feed Eurasian Skylark (*Alauda arvensis*) chicks in a nest close to its own. Conversely, a Wood Warbler has been seen to feed a young Tree Pipit. There are also documented cases of White Wagtails provisioning the fledged young of Common Redstarts and of a Yellow Wagtail feeding a juvenile Crested Lark (*Galerida cristata*). On the other hand, other species, such as the Eurasian Blackbird, sometimes "foster" wagtail young.

If a predator or intruder approaches an occupied nest or recently fledged young, the adult may perform a distraction display. The usual nature of this is that the adult drops down from the nest or flies out from it, and flutters to the ground, where it runs or flutters low, while calling, in an attempt to lead the intruder away from the nest. When this is successful, the bird then flies away. Sometimes, as it flutters, it drags a wing along the ground, as if injured. Such injury-feigning has commonly been recorded for the Meadow, Tree and Paddyfield Pipits, the Grey, Yellow and Cape Wagtails and most of the longclaws. The Rosy-breasted Longclaw will perform a distraction display even when the potential danger is 100 m from the nest. It makes low flights, with the legs dangling, perches on bushes while calling, and flies again. Distraction displays are given in response to the presence of dogs and snakes, as well as to humans.

Hatching success among pipits and wagtails in Europe ranges from 64% to as high as 90%. Various studies have found that, of those eggs that hatch, 71-88% usually produce fledged young, giving an overall success rate of 51-60%. In individual cases, this latter rate may sometimes be higher, up to 67% or more, and sometimes lower. In studies in Britain, for example, 42% of Grey Wagtail eggs produced fledged young, compared with figures of 53% for White Wagtails and 51% for Yellow Wagtails. In Ireland, however, almost 56% of Grey Wagtail eggs produced fledged young, while breeding success in two areas of Germany was, respectively, 53%, with 3·4 young fledged per pair per year, and 63%, with 3·3 young per pair per nest, this last figure being very high. Grey Wagtails in Denmark produced an average of three young per pair per year. In south Sweden and the Netherlands, Tawny Pipits appear to fit in well with this general pattern, successfully hatching about 80-89% of their eggs and rearing 60-74% of the chicks.

Studies of the Red-throated Pipit in different breeding areas revealed great variation in the species' hatching and fledging rates. Hatching success was 68·5% in Finland but 83·4% in the Yamal Peninsula, on the north-west Russian coast, while fledging success was only 62·9% at the Finnish sites but as high as 91·8% in the Yamal Peninsula. At the opposite extreme of this species' range, in the Chukotsk Penisula, in far north-eastern Russia, another study showed an overall success rate of 60·6%.

In one study of Tree Pipits, it was estimated that a mean of 2·4 young fledged per clutch, with pairs producing an average of 3·6 young in a season. In Britain, the average productivity of Tree Pipit pairs has been found to be 3·35 young, compared with figures of 2·2 for Meadow Pipits and 2·5 for Rock Pipits. In tropical and subtropical regions, where longevity may be much higher than in northern climes, and where the clutch is smaller, breeding success is often considerably lower. In South Africa, for example, S. E. Piper found that only 28% of eggs of Mountain Wagtails at sites on the Palmiet River, in KwaZulu-Natal, produced fledged young, giving an average annual productivity per pair of only 1·7-1·9 young. On the other hand, the annual adult survival rate was 95%, very much higher than that found for the Grey Wagtail in Europe, where only just over half of adults survive to the following year. Relatively few other data are available from Africa: from 16 clutches, totalling 55 eggs, a pair of African Pied Wagtails in Kenya reared 39 fledglings; and, as already mentioned, over a two-year period a Cape Wagtail laid 50 eggs, which produced a total of 29 fledglings.

Nest failure can occur at any stage of the nesting cycle. White Wagtails breeding in Britain are more prone to failure at the egg stage, and in south-west Ireland more Grey Wagtail nests failed

*The **Woodland Pipit** is a poorly known species that was formerly treated as a race of Long-billed Pipit* (Anthus similis). *The two are morphologically similar and have similar songs. The main difference is ecological, this form preferring tall but open miombo-type woodland and its widespread relative preferring rocky and shrubby hillsides. Very few details are known about the breeding of the Woodland Pipit: the nest is a grass cup and the clutch normally consists of 2-3 eggs, but that is virtually the extent of published knowledge. This photo suggests that the nest can be tucked away under a tussock and almost overarched by a roof of grasses.*

[*Anthus nyassae frondicolus*, Marondera, Zimbabwe. Photo: Peter J. Ginn]

at the egg-laying and incubation stages than did so later. Conversely, more Yellow Wagtails were lost during the nestling stage. Predation of Yellow Wagtails was found to increase during the later part of the fledging period, presumably because the young are noisier and the adults make more frequent visits to the nest. Breeding success in general seems to be higher later in the season, possibly because cover is denser, prey is more abundant and predators have a wider availability of prey. Conversely, later nests of Japanese Wagtails were found to suffer more from predation than earlier ones.

One reason for nest failure is inclement weather. Cold spells and snow early in the season can cause chilling of eggs or chicks when these are left unattended. In addition, high water levels following heavy rain often lead to the flooding of nests and the drowning of chicks of riverine species. Heavy rain can also have an adverse effect on ground-nesting species. The trampling of ground nests by domestic stock and game is a significant cause of nest failure among many species, such as the Yellow Wagtail in Europe and the Grassveld Pipit in Africa. Further, agricultural operations such as ploughing, the spraying of herbicide or the cutting of silage will affect all those species nesting on arable land or pastures. Brood parasites and predators also take a toll.

Cuckoos (Cuculidae) and cowbirds (*Molothrus*) are brood parasites of many species of pipit and wagtail, but not, so far as is known, of longclaws. Two cuckoo species, the Red-chested Cuckoo (*Cuculus solitarius*) of Africa and the widespread Common Cuckoo (*C. canorus*), concentrate on nests of motacillids. The Red-chested Cuckoo has two main host species, one of which is the Cape Wagtail. The Common Cuckoo has a number of hosts, but at elevations above 140 m it favours Meadow Pipit nests, while Tree Pipits and White Wagtails are also frequent hosts at lower altitudes. In Britain, up to 2% of Meadow Pipit nests and 4·5% of White Wagtail nests are parasitized by this cuckoo. Although Tree Pipits are parasitized infrequently in Britain, they appear to be more common hosts elsewhere in Europe, as in Poland and Russia, where in one study cuckoos accounted for as many as 7·5% of nest failures. Rock and Tawny Pipits are rarely or occasionally hosts to the Common Cuckoo, and this is also the case with Grey and Yellow Wagtails. For example, of 1946 clutches of this cuckoo in Britain, only three came from a Grey Wagtail nest, and just one of more than 200 nests found in Wales contained a cuckoo chick. Locally, the incidence of parasitism may be higher. In one area of the Netherlands, 6·2% of Yellow Wagtail nests were parasitized.

Outside Europe, the Common Cuckoo lays its eggs in the nests of such species as the Red-throated, Richard's and Paddyfield Pipits and the Citrine Wagtail. In north-east India, the renowned ornithologist and oologist E. C. Stuart Baker found that 7% of pipit nests were parasitized by the south Asian subspecies of this cuckoo. Another cuculid, the Himalayan Cuckoo (*Cuculus saturatus*), is known to parasitize Rosy Pipits in south-eastern Asia. In Africa, several species of cuckoo may lay their eggs in a pipit or wagtail nest. M. K. Rowan reported that Cape Wagtail nests were parasitized by two species, the Red-chested Cuckoo and the Diederik Cuckoo (*Chrysococcyx caprius*). In southern Africa, where there are three well-established "gentes" of the Diederik Cuckoo that parasitize the three commonest ploceids, each gens lays distinctive eggs; R. A. C. Jensen and C. J. Vernon thought that Cape Wagtails might be shown to be parasitized by a further well-defined gens. The nests of African Pied Wagtails, too, are parasitized by those same two species, as well as by a third, the Jacobin Cuckoo (*Clamator jacobinus*), and there is a record of a pair of African Pied Wagtails in Somalia fostering a young Klaas's Cuckoo (*Chrysococcyx klaas*). One Mountain Wagtail nest near Pietermaritzburg, in KwaZulu-Natal, was found to contain a Red-chested Cuckoo nestling, and this wagtail has also been recorded as a host of the Red-chested Cuckoo in East Africa. Finally, in North America, Sprague's Pipit sometimes acts as host to Brown-headed Cowbirds (*Molothrus ater*).

Predation, by a wide range of mammals, other birds and reptiles, is a significant cause of nest failure among motacillids. Indeed, predation accounted for 34% of failures of Tree Pipits in one study area and almost 50% of nest losses of White Wagtails. The commonest predators include rats, mustelids, foxes (*Vulpes*), corvids, small raptors and snakes, as well as domestic and wild felids. Brown rats (*Rattus norvegicus*) and other rodents are frequent predators of eggs and nestlings of most species. On South Georgia, the presence of rats on the main island may explain why the only local breeding pipit nests mainly on offshore islets. Rats are common along waterways in many regions, and in parts of Europe rats and feral American minks (*Mustela vison*), which

*The "black-and-white wagtails" and the "riverine wagtails" tend not to nest on level grassy ground. This **Grey Wagtail**, for example, has built its home in a classic site, a ledge on a damp rock face. This species commonly nests on ledges, at various heights above ground, and always close to water. The proliferation of man-made structures, such as bridges, stone walls and buildings, has allowed it to thrive where natural rock-faces are absent. In some regions the majority of Grey Wagtail nests are associated with artificial structures. The nest itself is a bulky platform topped with a cup of coarse material, lined with finer fibres, such as grasses, rootlets and hair.*

[*Motacilla cinerea cinerea*, Mangfalltal, Germany. Photo: Günter Ziesler]

are now widespread on European rivers, are believed to be the major predators of Grey Wagtails and several other river-breeding species.

Mustelids, snakes and corvids are serious predators of many bird species, including the Motacillidae. Nests of Japanese Wagtails, for example, are preyed on by *Elaphe* snakes, Siberian weasels (*Mustela sibirica*) and two species of crow (*Corvus*), as well as by brown rats, Asian field voles (*Microtus montebelli*), feral and domestic cats and Bull-headed Shrikes (*Lanius bucephalus*). In one study of Water Pipits in Europe, 39% of nests were preyed on by stoats (*Mustela erminea*) and snakes, whereas in another study of these pipits, in the Alps, long-tailed weasels (*Mustela frenata*) and deer mice (*Pesomyscus maniculatus*) were responsible for heavy losses of both eggs and nestlings. Mustelids, including both weasels and martens (*Martes*), along with corvids, Western Marsh-harriers (*Circus aeruginosus*) and Eurasian Buzzards (*Buteo buteo*), have been identified as predators of Tawny Pipits, up to 40% of the young of which are lost soon after fledging in Sweden and the Netherlands. In the Afrotropics, African monitor lizards (*Varanus niloticus*), snakes and small ground predators all commonly take the eggs or chicks of African motacillids, as well as preying on juveniles and breeding adults.

Various birds of prey, especially sparrowhawks (*Accipiter*), small falcons (*Falco*), harriers and buzzards, may all take nestlings and juveniles, as well as adults. Across the northern parts of Europe, Merlins (*Falco columbarius*) often specialize on Meadow Pipits, which form up to 70-80% of the falcon's diet on moorland and 40-50% of its diet around farmland in lower areas. In a study in north-east England, Meadow Pipits made up 48% of all birds taken by Merlins. This small raptor captures more juvenile pipits as the season progresses. In South Africa, an Amur Falcon (*Falco amurensis*) was watched as it devoured a Cape Longclaw, but it was not certain whether the small raptor had killed the longclaw or found it dead. In southern Africa, the remains of Cape Wagtails have been found several times in pellets of Common Barn-owls (*Tyto alba*), but it seems very unlikely that this or any other other motacillid features significantly in the diet of owls.

Otherwise, domestic pets, particularly cats but also dogs, account for many bird deaths. In South Africa, for example, a dog killed a Cape Wagtail that had been ringed nearly 3 years previously.

There are few records of parasites, such as lice (Mallophaga), fleas (Siphonaptera) or ticks, on motacillids, but blood-sucking larvae of the muscoid fly *Passeromyia heterocheta* and lice have been found on Cape Wagtail chicks. Blowflies (Calliphoridae) occasionally contribute to nestling mortality. Adult wagtails, especially White, Grey and Cape Wagtails, frequently suffer from a bacterial infection known as "bumble foot", resulting in swollen tarsi and feet, the infected birds often losing toes; the African Pied Wagtail also suffers from foot diseases. A trematode (*Tanaisia gratiosa*) was also found in a Grey Wagtail in China, and a trypanosome has been discovered in Welsh Grey Wagtails.

Rather few data are available on the longevity of most motacillids. There are records of Mountain and Cape Wagtails in Africa reaching, respectively, 10 and 11 years of age, with adult survival rate of the former sometimes as high as 95%. In Eurasia, motacillids are perhaps less long-lived, with most adults living for only two to three years. Exceptionally, Grey Wagtails and Yellow Wagtails have reached the respective ages of 6 years and 8·5 years. Importantly, juvenile survival is often low. In a study in north-west France, for example, juvenile mortality among Rock Pipits was found to be over 68%, the majority of the fledglings not surviving for more than four weeks.

Among the better-studied motacillids, including several of the wagtails, individuals breed for the first time when in their second year. This probably applies to the majority of the family, at least in the temperate parts of the range, but little is known about many of the tropical species.

Movements

Some members of the Motacillidae are highly sedentary, others make altitudinal or short-distance movements at the end of the breeding season, and some are regular long-distance migrants. For example, the South Georgia Pipit spends its whole life on South Georgia and associated islands. Those Grey Wagtails and Berthelot's Pipits living on the eastern Atlantic islands of the Canaries, Madeira and the Azores are also sedentary, as are some

*Some **Grey Wagtail** nests are hidden amongst vegetation but others, like this one, are very open and readily visible. In ideal habitat, 20-40 pairs of this species might pack along a 10-km stretch of river, with nests appearing on riverside rock faces every few hundred metres. The allocation of roles to sexes during the breeding cycle is relatively egalitarian in this species. Unlike many pipits, the construction phase is not the sole responsibility of females: some males carry nesting material and incorporate it into the structure, though they tend to visit the nest at a lower rate than their partners. Both sexes also contribute to incubation, though again females contribute slightly more than males. Males also provision the nestlings, as this photograph shows. Moreover, both male and female are liable to feign injury when they are disturbed near the nest. Interestingly, European studies have shown that the diet of young birds changes as they grow. At first, adults bring them soft-skinned larvae of mayflies, stoneflies, caddis-flies and diptera, but when their offspring have grown a little stronger, they bring late-instar invertebrates with tougher chitinous exoskeletons. General prey size increases through the nestling period too. Age-related shifts in diet are predicted by common sense, and are often suspected in the field, but few studies have proven them to be the case. The idea that they may be enforced by shifts in prey availability is disproved by the fact that the same general sequence is followed in consecutive broods.*

[*Motacilla cinerea cinerea*, Lancashire, England. Photo: Martin B. Withers/ FLPA]

Neotropical and Afrotropical species, notably the longclaws. At the other extreme, many of the species nesting in the Arctic tundra or taiga zones, such as the Red-throated, Pechora and Olive-backed Pipits, and in grasslands of the Palearctic Region, move thousands of kilometres southwards after breeding, spending the northern winter in Africa and the southern parts of Asia.

Several species are sedentary in parts of their range, but are partially or entirely migratory in other parts. For example, Grey Wagtails nesting in southern Europe and Morocco are largely sedentary, whereas those in Britain are partial migrants. Many leave Scotland and northern England after breeding and head south and south-west for the winter months, while others in southern Britain, as well as in Ireland, may be sedentary, at least in some years. All Grey Wagtails breeding in Scandinavia and east Europe are migrants, moving south or south-west to escape the long harsh winters. Other motacillids, such as Water Pipits which breed in mountainous regions, may undertake altitudinal movements, moving down from nesting areas to the lowlands for the winter months and ascending again as the snow melts in the spring. Similarly, Grey Wagtails in the Alps, the Elburz Mountains of Iran and the High Atlas Mountains of Morocco descend to lowland areas in the autumn, and Meadow Pipits likewise move from the uplands to the lowlands for the winter, some migrating farther south. The Water Pipit is of further interest in that some of the population breeding in the mountains of central Europe regularly make post-breeding movements in a westerly or north-westerly direction, spending the months of October to March in central and southern Britain (see also Habitat).

Long-distance migrants breeding in the western Palearctic move almost entirely to Africa. Eastern Palearctic motacillids mirror their western counterparts, travelling well to the south in the autumn. Eastern populations of the Citrine Wagtail, for instance, fly south to as far as Indonesia and New Guinea. Blyth's Pipit, breeding in Mongolia and surrounding regions, winters mainly in the Indian Subcontinent, while Richard's Pipit also winters there, as well as south and east to Indonesia, the Philippines and New Guinea. The Forest Wagtail, although breeding farther south in eastern Asia, is also wholly migratory, spending the non-breeding season primarily in South-east Asia and the Greater Sundas.

In the Nearctic, both the Buff-bellied and Sprague's Pipits are migratory. After breeding, they head south to the southern parts of the USA and to Mexico. Some Buff-bellied Pipits remain during the winter as far north as the Canadian border in the west and New Jersey in the east, but almost all Sprague's Pipits, a scarcer species, spend the non-breeding period in Mexico. Reflecting their origins (see Systematics), the small populations of Yellow and White Wagtails and Red-throated Pipits nesting in Alaska migrate back to the Old World, where they winter in eastern Asia south of Siberia. A few individuals of these species are occasionally recorded on the western seaboard of the USA.

Afrotropical motacillids are mainly sedentary, but some, such as the Cape Wagtail in South Africa, are partial migrants. The Golden Pipit is thought perhaps to make longer movements, as vagrants have been found far to the south of the normal range, and also to the north, in Oman. In addition, southern populations of the Grassveld Pipit, those breeding in Namibia, Botswana and South Africa, migrate to the east and north in the non-breeding season. Similarly, Mountain Pipits leave the Drakensberg Mountains, in the Eastern Cape, in March and return in October, hav-

*The **Forest Wagtail** is the most arboreal member of the family. It spends much of its time feeding on the ground underneath leafy canopies and, unlike all other motacillids, it habitually nests in trees. The nest itself is also unique; it is a small compact cup of leaves, twigs, fine grasses, and rootlets, bound together with moss and cobwebs. The outer layer is often interwoven with lichen or other natural material to provide camouflage. The usual nest-site is some 2-7 m above the ground, either balanced on a horizontal branch or lodged in an upright fork, often in quite open situations.*

[*Dendronanthus indicus*, Bikin River, Ussuriland, Russian Far East. Photo: Yuri Shibnev]

*In pipits, like the **Rock Pipit**, all incubation is undertaken by the female. Even after the eggs have hatched, she continues to brood and the male brings her food. Only when the chicks are a few days older do both parents share the role of provisioning. Female pipits are canny customers and their nests are difficult to find. They rarely land directly beside the clutch, and they often run some distance before flushing. Their circumspection makes sense in the light of the high predation pressure faced by most ground-nesting birds.*

[*Anthus petrosus littoralis*, Sweden. Photo: Victor Hasselblad/ VIREO]

ing probably spent the intervening months in areas north to north-west Zambia and southern DRCongo, and presumed migrants of this species occur also in Namibia, Botswana and Northern Cape Province. As in Europe and Asia, altitudinal movements are performed by some populations breeding at higher elevations, particularly by such species as the Short-tailed and Yellow-breasted Pipits and the Cape Longclaw in southern Africa. In several cases, motacillids may move away from very dry areas seasonally, as typified by the Golden Pipit and Sharpe's and Pangani Longclaws. Interestingly, some populations of the Short-tailed Pipit are present during or near the rains at latitudes between 4° S and 16° S mainly from September to March, and in central Africa from May to August, but this latter period coincides with the dry season in north-east Rwanda. Observations suggest that some movements in the Afrotropics, such as those made by certain populations of African Pied Wagtails and Plain-backed and Buffy Pipits, are probably nomadic or opportunistic.

Most motacillids migrate in flocks, in which family groups sometimes remain together. Wagtails and pipits have been described variously as either nocturnal migrants or diurnal migrants, but most migrate both by day and by night. In America, Sprague's Pipit is thought to migrate only by day, as its characteristic call has never been heard during the night. In Britain, flocks of Grey Wagtails are commonly seen in the daytime during the autumn, particularly in early September, off the south coast of Wales and south-east England, with some individuals heading out to sea. Peak movements occur mainly at the onset of anticyclonic conditions. A smaller spring passage is also evident. Small flocks of this species regularly cross the Mediterranean Sea at the Strait of Gibraltar, or fly across the Bosporus, in north-west Turkey. One observer at the latter station counted 285 Grey Wagtails as they passed eastwards by day between mid-August and late October, with passage reaching a peak at the end of September and early October. For birds moving down into north-east and eastern Africa, the Nile Valley and the Red Sea coasts are major flyways, but many others do migrate across the Sahara Desert.

Wagtails also migrate at night, as some appear at the lights of lighthouses. Through the Sahara and the deserts of the Middle East the Grey Wagtail is mainly a nocturnal migrant, but it stops off at oases during the night or during the day. Consideration of energetics suggests that Yellow Wagtails migrate non-stop over the Sahara, rather than making a series of short flights with resting stops, although adverse conditions can force them to make stopovers. Premigratory fattening in trans-Saharan migrants is well documented. It has been shown that Yellow Wagtails put on 30-40% of the body weight in fat before setting out on the return spring migration from north-east Nigeria to cross the Sahara Desert. The initial desert crossing is covered at a faster pace when compared with the later stages of the journey. The wagtails generally use the most direct routes between the breeding and non-breeding areas.

Yellow Wagtails time their departure from their African wintering quarters in accordance with the onset of spring in their breeding areas, rather than in response to rainfall in Africa. It has been suggested that moult, fattening and emigration are probably endogenously controlled, but competition from resident African birds may also be an important factor affecting the timing of migration.

Fidelity to a home area, or *Ortstreue*, is a widespread phenomenon among passerines. It can refer either to the previous breeding area or to a wintering area, or to both. A high degree of site-fidelity is exhibited by adult Meadow Pipits with regard to their breeding territories. While adults are site-faithful, returning constantly to the same breeding and non-breeding locations, younger birds are less faithful to the natal site. Although young Meadow Pipits usually return to an area near to the site where they were reared, they do sometimes move to localities up to 100 km away. In Malta, Grey Wagtails returned year after year to the same wintering area, one individual for four successive winters. There are many similar examples.

Few migrants among the Motacillidae reach Australia, although the Yellow, Citrine and Grey Wagtails occur there rarely. In western Europe, however, several eastern pipits are fairly regular vagrants in small numbers. These include the Olive-backed and Pechora Pipits and, more recently, Blyth's Pipit. Moreover, Richard's Pipit is a regular visitor in many European countries, and up to about 50 are recorded annually in Britain and Ireland. A small wintering population of these species is also present in the Middle East.

Relationship with Man

African Pied Wagtails, at least in part of their range, and both White and Japanese Wagtails have a close relationship with man,

*In the **Long-billed Pipit**, incubation lasts 13-14 days, and fledging another 13-14 days. The female works alone during the first phase, but both sexes contribute in tandem for the second, as seen here. The habitat shown is typical for this species, which often nests in the shelter of a tussock or rock on boulder-strewn slopes covered in xerophytic vegetation. Morphologically, the Long-billed Pipit is difficult to separate from the Grassveld Pipit* (Anthus cinnamomeus), *but the latter differs in display, voice and habitat, preferring grassy plains and meadows to rocky slopes.*

[*Anthus similis primarius*, Doornrivier, near Worcester, Western Cape, South Africa. Photo: J. J. Brooks/ Photo Access]

occurring in towns and villages, using buildings as nesting and roosting sites, and open lawns, roofs and other open spaces as foraging areas. For the large part, these birds are welcomed close to habitations. Trees planted in towns are popular roost-sites, as also are crops. Even boats and motor vehicles may be used as nest-sites, and so well liked are the wagtails that owners will give up using the vehicle while the birds complete their nesting; sometimes, the incubating wagtail will even tolerate car journeys.

On slow-moving rivers, the construction of weirs and mill-races and the building of canals and locks has enabled Grey Wagtails to spread into more lowland areas. Likewise, in the Canaries and the Azores, Grey Wagtails frequent wells and villages. In the Azores, any child caught harming a wagtail was punished, as the bird was linked to a religious belief.

In South Africa, the Cape Wagtail is regarded as a special, almost sacred bird, in close alliance with ancestral spirits. It is therefore not harassed. Any harm caused to a wagtail was thought to render the human responsible cattle-less. The wagtail was also believed to know and understand cattle; when feeding among them, it was said to be keeping a check on the number and condition of the stock. Few such beliefs exist in Europe, but wagtails are welcomed close to houses and are generally held in affection. The name applied to a wagtail in France, *bergeronette*, means "shepherdess" or "little maid"; thus, *Bergeronette des ruisseaux*, or the "shepherdess of the streams", clearly implies a fondness for the Grey Wagtail.

Few members of the family can be considered to be in any way a nuisance to man. They are, for the most part, small and unobtrusive birds, and it is difficult to imagine that any of the pipits could have any serious adverse impact on human interests. Wagtails often live in towns and villages, where they are generally left unmolested. Certain wagtail species, however, can at times cause problems. White Wagtails, on occasions when they gather to roost in commercial greenhouses in Europe, have been regarded as pests because of the damage that they do to crops. Similarly, large gatherings of roosting wagtails in trees in urban areas can occasionally become something of a nuisance to humans, because of the droppings deposited on the pavement below. On a minor scale, they can also cause local problems to householders, as when, for example, male Grey Wagtails repeatedly attack their reflections in windows. Many species also make a habit of regularly attacking car mirrors, attempting to drive away what they perceive as an intruder. This behaviour is widespread among White, Grey and Cape Wagtails.

Crops, especially irrigated crops such as rice, are much used by foraging motacillids, in particular by Yellow, Citrine and Grey Wagtails in Nepal and elsewhere. Further, Yellow Wagtails often nest in such crops as potatoes and cereals, this being a regular habit in some areas, as, for example, in the Lincolnshire fenlands of eastern England. These primarily insectivorous birds may be beneficial to the farmers in removing invertebrate pests.

Few motacillids are commonly kept in captivity, although some aviculturists do breed Grey Wagtails. One example of a fish-eating family of captive Grey Wagtails was mentioned earlier (see Food and Feeding).

Status and Conservation

As most pipits, wagtails and longclaws are open-country species, many of them have undoubtedly benefited from man's actions in clearing forests and woodland for agriculture. The New Guinea Pipit, for example, readily colonizes newly cleared areas, and the Yellowish Pipit in Brazil will move on to reclaimed land and fill-slopes with little vegetation. Arable and fallow fields and grasslands attract an array of pipits in Eurasia and Africa, and cattle attract large flocks of Yellow Wagtails during passage and in the non-breeding season. In some instances, overgrazing and regular burning may be inimical, but many pipits are drawn to recently burnt ground.

Few motacillids can be considered endangered, but some have very restricted ranges and, as such, are vulnerable to habitat changes. In 1994, only the Ochre-breasted Pipit of South America and the Yellow-breasted and Sokoke Pipits of Africa were listed as globally threatened, with a further six motacillids considered Near-threatened. In the most recent "official" publication on the conservation status of the world's avian species, however, five motacillids are classed as globally threatened, two of these being Endangered and three Vulnerable. The two Endangered species are both African: the Sokoke Pipit, found in a few coastal forests in East Africa, and Sharpe's Longclaw, lo-

*When a female **Grey Wagtail** approaches her nest, carrying an insect for her brood, she flies silently. This photograph captures the elegant lines of her body, the elongated tail and tertials to match. It cannot show, however, the fact that the flight of wagtails is one of their most distinctive features. All members of* Motacilla *fly strongly but with an exaggerated undulation; a burst of rapid wingbeats, followed by a curving dive, and so on. The larger pipits also bound in flight, but less dramatically. With her unique pattern of plumage and flight, a Grey Wagtail disappearing downstream is usually distinctive, especially coupled with the loud metallic "tchik" call, which is used freely away from the nest.*

[*Motacilla cinerea cinerea*, Navalmoral de la Sierra, Avila, Spain. Photo: Juan Manuel Hernández López]

cally distributed in montane grassland in the Kenyan Highlands. One of the three Vulnerable species is also African, the Yellow-breasted Pipit being confined to upland grasslands of South Africa and Lesotho. The other two are Sprague's Pipit, which breeds on prairie grasslands in North America, and the Ochre-breasted Pipit, restricted to *campos* grassland in eastern South America. A further four species are now placed in the Near-threatened category, because of their restricted ranges and apparent population declines or pressures on their grassland habitat. These are the Abyssinian Longclaw (*Macronyx flavicollis*) and the Nilgiri (*Anthus nilghiriensis*), South Georgia and Malindi Pipits. Finally, an additional two African species, the Long-tailed Pipit and Grimwood's Longclaw, are placed in the category of Data-deficient.

In South America, the Chaco Pipit, as well as the Ochre-breasted Pipit, was formerly considered to be under threat or

*The breeding system of longclaws seems extremely similar to that of other motacillids: incubation and nest-building is conducted mostly or solely by the female; nestlings and fledglings are tended by both parents for anything up to nine weeks after hatching. Here, we see proof of biparental care in the **Yellow-throated Longclaw**: the adult male is bringing a large insect for his brood. The chicks themselves, about a week old, have sprouted a dense mat of juvenile plumage, have lost many of their initial down feathers, and are no longer blind.*

[*Macronyx croceus vulturnus*, Marondera, Zimbabwe. Photo: Peter J. Ginn]

*Few motacillids breed at higher latitudes than the **Pechora Pipit**. It nests in shrub tundra and the broad, boggy valleys of Siberia, and its breeding season is thus delayed until the summer melt is in full swing. It lays clutches containing 4-5 eggs in late June or July; the short Arctic summer sometimes allows just enough time for two consecutive broods. In optimum habitat, breeding pairs are so tightly clustered that they have been considered to form loose colonies. The breeding range freezes over in winter and the Pechora Pipit is forced to migrate; the wintering grounds are poorly known, with most non-breeding records coming from eastern Indonesia.*

[*Anthus gustavi*, Russia. Photo: Yuri Artukhin/FLPA]

declining and, therefore, of high conservation priority. Further fieldwork by H. E. Casañas and colleagues, however, has shown that the Chaco Pipit is fairly common to common in its breeding area, in central Argentina. It migrates northwards up to Paraguay and northern Argentina, where it has been found in the provinces of Formosa, Chaco, Corrientes and Misiones. The Ochre-breasted Pipit has been downgraded from Endangered to Vulnerable, since recent surveys have found the species to be more common and widespread than was previously believed. Nevertheless, it is still threatened, especially in Brazil, where dramatic declines have occurred.

Grasslands are crucial to many motacillids, in particular the two *Hemimacronyx* species, namely the Yellow-breasted Pipit and Sharpe's Longclaw. More than 58% of the South African grassland biome was, however, irreversibly transformed between 1984 and 1990. The planting of alien trees on grasslands not only causes direct loss of habitat, but also fragments pockets of remaining grassland. Loss of grassland to afforestation is considered the main threat to the Yellow-breasted Pipit. It has been estimated that 50% of the species' population may be lost through commercial afforestation of grasslands if no conservation action is taken. In Lesotho, Yellow-breasted Pipits are rare and are known only from Sehlabethebe National Park, where several hundred have been recorded. The overly frequent burning of grasslands and overgrazing and trampling by small livestock, especially in Lesotho and the eastern parts of Eastern Cape Province, are also threats. Even though conservation of grassland is essential for its survival, less than 5% of this habitat is formally protected in South Africa.

Appropriate management of remaining grasslands is vital for species such as the Yellow-breasted Pipit and Sharpe's Longclaw. Grassland management practices on the Wakkerstoom high-altitude grasslands of South Africa have been shown to affect the nesting success of Yellow-breasted Pipits, through influencing the cover, height and density of vegetation. Nests in plots with low-intensity grazing and biannual burning had the highest success, and those in heavily grazed, annually burnt plots the lowest success, but nest density was highest in lightly grazed, annually burnt plots. Nest survival over the whole nesting period was lowest in heavily grazed, annually burnt plots, intermediate on lightly grazed, annually burnt plots, but highest in lightly grazed biannually burnt plots. In summary, the burning regime and the grazing intensity influence the amount, density and height of vegetation, nests being more successful with more vegetation cover, taller vegetation, higher vegetation density and lower heterogeneity. There is, therefore, a need to maintain low-intensity pastoral farming and to encourage appropriate management of grasslands.

The world population of the Yellow-breasted Pipit was estimated at 1500-5000 individuals in 1992, but the figure was increased to between 2500 and 6500 individuals in 2000. The species' habitat is highly fragmented, and further fragmentation would certainly be detrimental. Approximately 10% of the population is located within protected areas, mostly in the Natal Drakensberg National Park. The proposed grassland biosphere reserve in the area of Wakkerstroom is believed to hold up to 30% of the global population.

Sharpe's Longclaw, confined to Kenya, is also dependent on sympathetic grazing regimes. Its range is already small and fragmented, and there is concern about the continuing rate of habitat degradation and population decline. The species is found mainly on the Kinangop Plateau, Mau Narok and Uasin Gishu grasslands, and it has been recorded also on the eastern slopes of Mount Elgon, the grasslands of Nandi District and the northern drier slopes of Mount Kenya, but there are no recent records from the Aberdares. It is still locally common, as illustrated by the fact that a density of 40 birds/km^2 was recorded in 1996 on the Kinangop Plateau, but it requires tussocks and short grass. Land-use changes, especially cultivation, tree-planting and the removal of tussock species by ploughing, pose a serious threat to this restricted-range motacillid. The increasing human population results in smaller landholdings and higher stocking rates, rendering the grassland unsuitable for the longclaws.

Grassland management is critical for some other species, too, notably the globally threatened Sprague's and Ochre-breasted Pipits and Near-threatened species such as the Malindi Pipit. Sprague's Pipit was placed in the Vulnerable category because it has undergone a rapid population decline on its breed-

ing grounds in the North American prairies. Since 1970, its numbers have decreased by 4·7% annually. In the USA, the rate of decline reached a peak of 52% in a ten-year period in the 1960s and 1970s, but has fallen somewhat since then; in Canada, however, it has increased since 1975, to 8% per year. The main threat to the species is loss of prairie habitat, usually through conversion to seeded pasture, hayfields and cropland, and intensive grazing. The pipit shows a positive association with cover of standing dead vegetation less than 10 cm in height; the taller vegetation and the increased amount of bare ground found in non-native pasture probably make this less attractive to Sprague's Pipit. Since 1900, about 75% of the Canadian prairies have been converted for more intensive agriculture. Other threats include loss of, and degradation of, both breeding and wintering habitats. Overgrazing and burning can have an adverse impact on the habitat, and hay-cutting destroys nests; furthermore, burning damages the habitat in the first year, although, since it reduces the number of woody plants, it generally has positive impacts in later years. Sprague's Pipits need well-drained open grasslands with sparse to intermediate grass density and a moderate depth of litter. Encroachment into grasslands by shrubs and trees in the breeding and non-breeding areas may also be a local problem. In its wintering quarters in Mexico, Sprague's Pipit is under threat owing to fragmentation of grasslands through encroachment of woody vegetation, and widespread overgrazing. The illegal poisoning of prairie dogs (*Cynomys ludovicianus*) and the resultant degradation of their "towns" is also making some grassland inimical to species such as Sprague's Pipit. Although most of the prairie habitat is unprotected, large areas are in military reserves and national parks and on Prairie Farm Rehabilitation lands.

The habitat of the Ochre-breasted Pipit in Brazil has been heavily modified or altered, mostly since 1950. By 1992, some two-thirds of the *cerrado* region were no longer suitable for this species, having been subject to intensive grazing, invasion by other grasses, annual burning, or conversion to crops such as soybeans, eucalypts (*Eucalyptus*) and others. This pipit requires dry grassland or short grass in lightly grazed areas; it cannot tolerate annual burning. In Argentina and Paraguay, too, habitat modification, especially the conversion of natural grassland to eucalypt forest, is a significant threat. Flooding of habitats caused by the creation of new dams, such as that at Yacyretá, in Paraguay, is also of concern.

In an earlier South African publication, the Mountain, Yellow-tufted, Short-tailed and Yellow-breasted Pipits and the Rosy-breasted Longclaw were red-listed, as they were considered threatened or near-threatened. The Mountain Pipit, however, was removed from the *Eskom Red Data Book*, published in 2000, since current data suggest that it is not under any threat. The Long-tailed Pipit may be at risk, but so little is known about its population size and its movements that it is currently placed in the conservation category of Data-deficient.

In Europe, only one of 13 species of motacillid was considered regionally at risk by W. J. M. Hagemeijer and M. J. Blair, all others having a favourable conservation status and secure populations. The one species that had suffered marked declines since the mid-1960s, and was considered vulnerable, was the Tawny Pipit. It now occurs only in small isolated breeding sites in central Europe, although it is more common on inland sand dunes, clearings and open-cast mines on sandy soils. The reason for the decline was thought to be habitat loss caused by agricultural intensification, afforestation and scrub encroachment of open areas. The Tawny Pipit's strongholds in Europe are in Spain, Italy and Ukraine. Agricultural intensification of former low-intensity farming or steppe areas may well lead to further declines. In north-east Ukraine, however, Tawny Pipits appear to tolerate overgrazing, erosion, quarrying and the early stages of afforestation. In this area the species has two main breeding habitats, one of which is chalk grassland and the other sand dunes in river valleys. Transect counts in chalk grassland revealed that Tawny Pipit abundance was related mainly to two habitat parameters, namely the mean height of vegetation and vegetation cover. The pipits prefer short vegetation and sparse cover with areas of bare ground. Furthermore, there appears to be a negative correlation between the abundance of the Tawny Pipit and that of the Tree Pipit in places where the two overlap.

Because of its restricted distribution and sedentary nature, Berthelot's Pipit could appear to be at risk. Nevertheless, although it is confined to the Madeiras, the Selvagens and the Canaries, in the east Atlantic, it is a common bird on these islands. Historical reports indicate that it was always very numerous throughout its range. One ornithologist, when revisiting

*A brood of five is a common phenomenon in the **White Wagtail**. Given that so many hungry mouths compete to receive food from two overworked adults, it is not surprising that a signalling system has arisen. The gape of nestling wagtails is bright red, as it is in most passerines. The available evidence suggests that the tone of red is related to blood supply, and this in turn is related to hunger, such that the gape reddens the longer a chick goes unfed. Coupled with loud begging calls, the red gape of nestlings is a signal to (and target for) the visiting adults. In some species, such as longclaws, the red signal is accentuated with sharply contrasting white markings called guide spots.*

[*Motacilla alba alba*, Los Alcornocales Natural Park, Cádiz, Spain. Photo: Víctor M. Guimerá]

*These **Grey Wagtail** nestlings are very close to fledging, suggesting that they are about 11-13 days old. Once they leave the nest they will be tended by both parents for at least two weeks, unless the female quickly lays a second clutch, in which case the male will take sole responsibility for feeding the first brood. Repeat broods are usually laid 1-2 weeks after fledging, but some females begin their second clutch just one day after their first brood has fledged. On rare occasions, a youngster from the first brood will help its parents feed the second. In the temperate zone, both productivity and breeding success are surprisingly high in Grey Wagtails.*

[*Motacilla cinerea cinerea*, Biscay, Spain. Photo: José Luis Gómez de Francisco]

Gran Canaria in 1963, thought that the pipit had become less common there when compared with his impressions gained in 1908-1920. He attributed this perceived decline to the spread of artesian wells and tomato cultivation, with consequent widespread use of pesticides. Currently, the species is still common in suitable habitat on Madeira and in the Canaries, where, in 1990, ten breeding pairs were found in 2·7 ha on Lanzarote. Recent estimates are of 15,000-20,000 individuals in the Canaries, probably 50 breeding pairs on Selvagen Grande, and 500-1000 breeding pairs on Madeira. The population is considered stable and is not at present threatened, but future developments could impinge on its habitats.

Yellow Wagtails in Britain suffered a contraction of range between the 1960s and the early 1990s. Local declines were noted both there and in a dozen other countries in Europe, but elsewhere in the continent populations are stable or, as in Sweden

*In all motacillids studied thus far, both parents provide the nestlings with food and both remove faecal sacs. In the early stages, when nestlings are young and faecal material is small and soft, the sacs are removed and swallowed immediately. Later, when the sacs are bulkier and tougher, they are carried from the nest and dumped. Here we see that a nestling **Yellow-throated Longclaw** has just excreted faecal material, which the adult is about to dispose of elsewhere. By keeping the nest and its environs free of droppings, the parents maximize hygiene and minimize the likelihood of attracting the attention of predators.*

Few land-use changes disrupt grassland ecology quite as much as afforestation, and indeed this is one of the major threats to India's only endemic motacillid, the ***Nilgiri Pipit****. The natural grasslands that once covered the slopes of the Nilgiri Hills, in the Western Ghats, are increasingly planted with* Eucalyptus, Acacia *and tea. The resultant habitat is unsuitable for this bird and its inclusion in the Near-threatened category is based on the consequent contraction of its effective range and numbers. Grassland frequently tends to be overlooked as a conservation issue, and it is vital that it be incorporated into networks of protected areas, in all relevant zones.*

[*Anthus nilghiriensis*, Eravikulam National Park, Kerala, India. Photo: Tim Loseby]

and Slovenia, increasing. In Britain, surveys on waterways suggested a decline in abundance of as much as 81%, and data from nest record cards indicated that the average brood size of this wagtail fell from 4·85 to 4·4 eggs over the 30-year period up to the year 2000. This decrease in brood size may partly explain the decline in numbers, but habitat changes may also be implicated. Agricultural intensification, involving heavy use of pesticides and loss of natural vegetation, leads to fewer insects and other invertebrates, and has been linked, as noted above, to declines in Tawny Pipit numbers in Europe. Despite this, high wagtail densities occur on intensively farmed arable land in the Netherlands. Yellow Wagtails and other wet-grassland or wetland-edge species are at risk, too, from the drainage or other loss of natural wetlands, although this has been partly offset by the creation of artificial sites, such as small farm dams, drinking-water reservoirs and sewage ponds.

Other wagtails, pipits and longclaws dependent on wet grassland in Eurasia, Africa or the Americas would clearly suffer if these habitats were lost or damaged, as through drainage and intensive crop production. In Zambia, for instance, drainage of dambos may be a local threat to Fülleborn's Longclaw. Similarly, wetland drainage is believed to be the reason for the contraction in range of Rosy-breasted Longclaws in South Africa.

Afforestation of open areas will, of course, have an adverse effect on grassland species. This has happened in India, where the planting of eucalypts, other trees or tea bushes on mountain grassland in the Kerala Hills has led to a reversal in the fortunes of the Nilgiri Pipit, which is now considered Near-theatened. Other species can suffer from the conversion of native woodland to conifer or gum plantations. In north-west Europe, for example, the planting of conifers on *Calluna* moorland causes declines in the numbers of Meadow Pipits. Planting may, however, benefit certain arboreal species such as the Tree Pipit, at least in the short term. Tree Pipits readily colonize new conifer plantations, but they usually abandon these after four or five years as the trees mature and the canopy closes; even so, they do use older plantations and the forest edges in some areas of north-west Europe. Coppicing of broadleaf woodland can also create temporarily suitable habitat for this species. Conversely, it seems probable that some forest-dwelling motacillids are adversely affected by deforestation. Nevertheless, there is no evidence that Forest Wagtails, which are dependent on trees in Asia, have undergone any decline.

Loss of riparian trees may have an impact on Grey and Mountain Wagtails through changing the nature of watercourses and, at the same time, affecting food supply. Ironically, Tree Pipits on their non-breeding grounds in Africa may have benefited from "low-key" forest clearance for crops. This small-scale clearance often leaves scattered trees, providing ideal habitat for this species.

Around 1·5 million years ago the ancestor of today's Correndera Pipit (Anthus correndera) *arrived on South Georgia. During subsequent millennia, evolution has given rise to a new endemic form, the* ***South Georgia Pipit****. Unfortunately, it is now classified as Near-threatened. Its population has crashed due to predation by brown rats* (Rattus norvegicus), *an introduced pest that tends to thrive on oceanic islands by devouring large numbers of eggs and nestlings. As a result, only 3000-4000 South Georgia Pipits survive, most of them confined to some 20 rat-free offshore islands.*

[*Anthus antarcticus*, Gold Harbour, South Georgia. Photo: Greg Lasley/VIREO]

*The **Abyssinian Longclaw** was once thought to be a common bird on the high plateaux and open grassland of Ethiopia. During recent surveys, however, it was found to be locally distributed and generally scarce, and its status has consequently been modified to Near-threatened. It seems likely to be under pressure from a growing human population, with the associated expansion of agriculture and increase in grazing pressure. Given the shortage of accurate information regarding its population and distribution further surveys are urgently required.*

[*Macronyx flavicollis*, Dinsho, Ethiopia. Photo: Dick Forsman]

One globally Endangered forest species that has undoubtedly suffered from habitat loss is the Sokoke Pipit. This localized motacillid has suffered greatly from human encroachment into the Kenyan and Tanzanian coastal forests. It is currently known to survive only in seven localities. The Arabuko-Sokoke Forest Reserve, in Kenya, is its main stronghold. The Tanzanian population is very low, the species being very rare at all known sites. Indeed, the Moa population is probably extinct, as none was found during a 1992 survey at Kilulu Hill, where only 2 km^2 of forest remain. Nor were any seen in Kazimzumbwi Forest Reserve, on the Pugu Hills, in 1990, but, as one was seen in October 1994, a few individuals may survive there; this reserve is separated from Pugu Forest by only a narrow strip of cleared land up to 1 km in width. In September 1989, two individuals were caught in the Kiono Forest Reserve, in north-east Tanzania. These were the first Sokoke Pipits recorded in the country since 1938, and their capture then increased the known localities of the species in East Africa to four. Two months later, two Sokoke Pipits were observed in Vikindu Forest Reserve, 17 km south of Dar es Salaam, and another was seen in Kiono Forest in March 1990. Although rare at both reserves, the species is the target of conservation efforts there. It has since been located also at Dondwe Forest Reserve, near Vikindu, and at Dar es Salaam.

Many coastal forests in East Africa have disappeared or become degraded through logging and encroachment for crops, grazing and firewood. Some forests in the Pugu Hills were cleared at the end of the 1970s, to make way for a brick factory and a kaolin mine, and only 10 km^2 of the original 22-km^2 Pugu Forest Reserve remained at the start of the 1980s. In the species' stronghold, in the Arabuko-Sokoke Forest, it occurs at densities of up to one pair per 2 ha in *Afzelia*-dominated forest, but at lower densities in thickets within degraded areas and in other wooded habitats. In 1979, it was estimated that the forest held 3000-5000 pairs of Sokoke Pipits; in 1984, the population was believed to be at least 2000 pairs. Recent studies in the *Brachystegia* areas of the forest revealed a density of 2·8 birds/ha in undisturbed forest, much higher than the 0·9/ha recorded in logged-over forest. Some 13,000 pipits were estimated to occur in the *Brachystegia* component, far more than had hitherto been thought, but the authors concluded that the existence of the Sokoke Pipit is probably compatible only with very limited forest exploitation.

Although an area of 400 km^2 of Arabuko-Sokoke may appear to be protected by its status of a forest reserve, logging and replanting with exotic species is not illegal. Some 43 km^2 are fully protected as a nature reserve, but legal regulations are often ignored. Encroachment by people and livestock also contributes to the further degradation of the habitat. Lack of funds for forest officers has been an added problem. There have been pressures to clear part of the Arabuko-Sokoke Forest for cultivation, but a presidential statement in 1998 reaffirmed the conservation status of the forest.

*Over the last century the grasslands of Brazil, Paraguay and Argentina have been heavily modified, and much of the original area is now no longer suitable for the **Ochre-breasted Pipit**. This species requires relatively dry natural grassland, and prefers a mosaic of burnt areas and short turf. This habitat has declined in extent and quality due to excessive grazing, burning and afforestation, and because it has been converted to crops such as soybeans and sugar cane. These changes in land use have caused a major decline in the range and population of this pipit, and it is now classed as Vulnerable.*

[*Anthus nattereri*, Serra da Canastra, Minas Gerais, Brazil. Photo: Edson Endrigo]

Sprague's Pipit *is the only member of the family with a breeding range restricted to North America. Unfortunately, it has declined rapidly owing to the conversion of native prairie to intensively farmed cropland: 70% of Canadian prairie has been lost since 1900, and the figures are not much prettier in the USA. Grassland in the wintering range is becoming increasingly fragmented, overgrown and overgrazed. Although a few populations are protected in military reservations and national parks, the species is Vulnerable to extinction and a concerted cross-boundary effort is required to safeguard its future.*

[*Anthus spragueii*, Kidder County, North Dakota, USA. Photo: Brian E. Small]

Pollution of rivers might be expected to have an adverse impact on the Grey and Mountain Wagtails, which obtain their prey partly from watercourses. In the UK, however, little evidence was found for any adverse effect of acidification on Grey Wagtails; in contrast to dippers, the catholic diet of the wagtails, coupled with opportunism, enables them to survive on acidic or otherwise polluted streams and rivers. S. J. Peris and co-workers also found that Grey Wagtails were poor bio-indicators of the chemical quality of Mediterranean watercourses.

Modification of rivers through dam-building, canalization and over-abstraction of water results in the loss of such habitat features as riffles, exposed rocks and overhanging trees, which, in turn, leads to large-scale losses of natural food resources. Wagtails that breed and feed in the riparian corridor are likely to suffer as a consequence. On the other hand, motacillids such as the White and African Pied Wagtails may actually benefit from the construction of reservoirs, as these provide a longer shoreline than that of the original watercourse. The latter species, however, appears to have declined in Egypt. Until the early twentieth century, it was regularly reported in small numbers along the River Nile northwards to the first cataract, near Aswan, where it was regarded as common, but the only recent report from Aswan was of a single individual in March 1980; there have been several recent records in the autumn, winter and spring from between Aswan and Wadi Halfa, in Sudan, and the species is probably a rare breeding resident along the shores of Lake Nasser. Several other motacillids, including the newly discovered Mekong Wagtail and the White-browed Wagtail, inhabit those lowland stretches where the river is braided and where there are numerous shingle shoals and sandbanks. Were these stretches of river to be submerged under new reservoirs, then populations of these species would suffer locally.

Another type of threat, more insidious, is the aerial spraying of chemicals. In Africa, Fenthion is used as a means of controlling Red-billed Queleas (*Quelea quelea*) when they are at roost in reedbeds and trees by water. Such habitats are used also by roosting White, Cape, Yellow and African Pied Wagtails. Tens of millions of queleas are killed each year by chemicals or by fuel explosions at roosts, but the effects of thee control methods on non-target species are very poorly documented. Crop-spraying, too, is a potential danger. One incident in southern Somalia involved the death of twelve Yellow Wagtails after a banana plantation was sprayed.

The damage that can be caused by the uncontrolled use of pesticides is well documented in the literature. In a further case, the potentially disastrous effect on Berthelot's Pipit of the use of rodenticide to protect nesting seabirds on Salvagen Grande was, fortunately, minimized by the undertaking of comprehensive pre-application studies.

Finally, one can only speculate about the impacts of climate change on the environment and on wildlife of all kinds. If drier conditions prevail farther north in Europe, for instance, then Mediterranean species such as the Tawny Pipit may extend or shift their ranges to the more northerly parts of that continent. Loss of tundra habitat as a result of ice melt, on the other hand, would have a serious impact on Red-throated and Pechora Pipits, perhaps even putting their very survival at risk. Conversely, milder winters in Europe would result in higher survival of such species as the Grey and White Wagtails, which sometimes suffer heavy losses in severe winters, as happened in 1962/63. Recent research suggests that Sprague's Pipit is one of the North American grassland species potentially most vulnerable to global warming. Models predict that this globally threatened pipit could possibly be extirpated from most of its current range in the USA and southern Canada. Similarly, global warming may have a negative impact on alpine breeding populations of the Buff-bellied Pipit in the Nearctic Region.

Sharpe's Longclaw *is endemic to Kenya, where it inhabits montane regions and Rift Valley escarpments. It requires damp grassland with short and tussocky turf, habitat characteristics favoured by low-intensity pastoral farming. It remains locally common on the Kinangop Plateau, and possibly elsewhere, but no population receives official protection, and fewer than 10,000 birds are thought to survive. Its numbers are being driven ever lower by detrimental land uses, foremost amongst which are afforestation, the expansion of agriculture, and the intensification of livestock grazing. These threats combine to place this taxon in the Endangered category.*

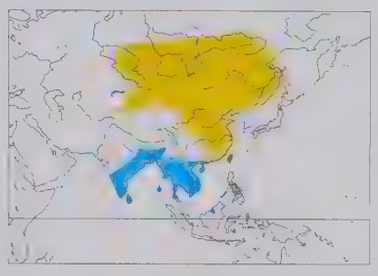
Genus *ANTHUS* Bechstein, 1805

1. Australasian Pipit

Anthus novaeseelandiae

French: Pipit austral **German**: Australspornpieper **Spanish**: Bisbita Neozelandés
Other common names: Common/New Zealand Pipit; Australian Pipit (Australian and New Guinea races)

Taxonomy. *Alauda novae Seelandiae* J. F. Gmelin, 1789, Queen Charlotte's Sound, South Island, New Zealand.
May form a superspecies with *A. richardi*, *A. rufulus* and *A. cinnamomeus*, and all were formerly treated as conspecific; recent DNA studies, however, do not support a close relationship between them. New Guinea and Australian races often considered to represent a separate species; also, recent evidence suggests that some populations on offshore islands may merit subspecific or even specific status. Described race *subaustralis* (from WC Western Australia) merged with *australis*; likewise, *reischeki* and *taupoensis* (both North Island, New Zealand) synonymized with nominate. Nine subspecies recognized.
Subspecies and Distribution.
A. n. exiguus Greenway, 1935 - EC New Guinea.
A. n. rogersi Mathews, 1913 - coastal NW Australia E to Cape York Peninsula.
A. n. bilbali Mathews, 1912 - SW Western Australia and SC South Australia.
A. n. australis Vieillot, 1818 - WC, C, E & SE Australia.
A. n. bistriatus (Swainson, 1838) - Tasmania, and islands in Bass Strait (King I, Flinders I).
A. n. novaeseelandiae (J. F. Gmelin, 1789) - New Zealand.
A. n. chathamensis Lorenz-Liburnau, 1902 - Chatham Is.
A. n. aucklandicus G. R. Gray, 1862 - Auckland Is.
A. n. steindachneri Reischek, 1889 - Antipodes Is.



Descriptive notes. 17-18 cm. Large, well-built, slender-billed pipit with streaked underparts. Nominate race has narrow white supercilium, dark eyestripe faint in front of eye, broad and prominent behind eye, narrow dark moustachial and malar stripes, whitish submoustachial stripe; ear-coverts pale brown or fawn; fulvous-brown above, feathers with blackish centres and buff-cinnamon margins, giving streaked and mottled appearance, rump almost plain; remiges dark brown, edged fulvous, greater wing-coverts and inner secondaries broadly margined fulvous-white; tail brown, T5 with white outer web and distal half of inner web, T6 mostly white; white throat and foreneck; neck side and breast fulvous-white, mottled dark brown, abdomen, flanks and undertail-coverts white, flanks lightly streaked dark; iris dark brown; bill pale to dark brown, or horn, lower mandible with pinkish or horn base; legs pale pinkish-brown to yellowish-brown. Sexes alike. Juvenile resembles adult. Race *chathamensis* differs from nominate in having buffer feather edging and underparts; *aucklandicus* is more fulvous above and below, with almost no white on underparts, has bill stouter, supercilium obscure; *steindachneri* is more fulvous than previous, dark brown with light brown feather edging above, outer half of T5 and T6 cream, throat and breast cream with few brown streaks, abdomen light pinkish-brown; *rogersi* is small, with proportionately long tarsus, cold medium dun-brown above, remiges edged brownish-cream, breast heavily spotted blackish, spots may extend to upper belly; *exiguus* is similar to last, but with deeper and duller black markings; *bilbali* is large, with proportionately short tarsus, dull tawny-brown above, remiges edged brownish-cream with russet cast, inner rectrices edged tawny above, breast and belly deep cream, heavy breast streaking sometimes extending to upper belly and flanks; *australis* is medium to large, with proportionately short tarsus, dull tawny to sandy brown above, remiges edged brownish-cream, moderate to sparse streaking on breast rarely extending to flanks and upper belly; *bistriatus* is large, with proportionately long tarsus, deep tawny-brown above, remiges edged brownish-cream with russet cast, inner rectrices dusky with tawny edges, breast and belly cream, breast streaking rarely extending to belly and flanks. Voice. Song, in flight, a short descending trill or a quavering, trilled "tiz-wee-ir". Plaintive sharp "chirp" or "chirrup" call; also rendered as brisk splintered "pith" or rasping drawn-out "zwee" or "tsweeer".
Habitat. Any open, short grassland, as well as roadsides, coastal dunes and clearings in forest; often on man-modified grasslands, e.g. airstrips, gardens and playing fields. Quickly colonizes newly cleared areas.
Food and Feeding. Insects, small crabs and other invertebrate prey, and grass seeds. In 80% of 57 gizzards in one study, invertebrates comprised 90% or more of food by volume: c. 77% contained beetles (Coleoptera), 67% Hymenoptera (mostly ants), 63% flies (Diptera), 39% insect larvae, 25% insect pupae, 25% spiders (Araneae), 18% orthopterans, 14% lepidopterans and 12% bugs (Hemiptera); one feather louse (Mallophaga), one aquatic snail (Mollusca) and one isopod (Crustacea) also found. Also many seeds, of following plant families (in order of importance): clovers (Leguminosae), grasses (Gramineae), Compositae, Plantaginaceae, Cyperaceae, Polygonaceae, Labiatae, Cruciferae, Caryophyllaceae, Ranunculaceae, Rubiaceae. Forages on ground, picking food items from surface. In flocks of up to c. 60 in non-breeding season.
Breeding. Mainly Aug-Dec, but recorded in all months; may have 2-3 clutches per year. Sings in undulating display-flight. Nest a deep grass cup, lined with softer grass, built in sheltered depression, often on bank or slope. Clutch 2-5 eggs; incubation by female, male keeping watch, period c. 13 days; young fledge after c. 14 days.
Movements. Largely sedentary or locally nomadic, but some redistribution occurs between the summer and winter months. In Australia, only a non-breeding visitor in Kimberley area of N Western Australia. Flocks of up to 100 individuals recorded outside breeding season, suggesting local movements.
Status and Conservation. Not globally threatened. Generally common to very common. Very common in grasslands in W & SE Australia, where densities of 0·07-0·22 birds/ha recorded; particularly abundant on high plains of the Great Dividing Range; rather sparse through C & N Australia. Very common in Tasmania and in New Zealand. Has benefited generally from clearance of land for agriculture. In some parts of range may be considered locally as a nuisance; reported to damage vegetables in Australia.

2. Richard's Pipit

Anthus richardi

French: Pipit de Richard **German**: Spornpieper **Spanish**: Bisbita de Richard

Taxonomy. *Anthus Richardi* Vieillot, 1818, France.
May form a superspecies with *A. novaeseelandiae*, *A. rufulus* and *A. cinnamomeus*, and all were formerly treated as conspecific; recent DNA studies, however, do not support a close relationship between them. Race *ussuriensis* considered by some authors to be synonymous with *sinensis*. Five subspecies recognized.
Subspecies and Distribution.
A. r. richardi Vieillot, 1818 - breeds SW Siberia and NE Kazakhstan E to L Baikal; winters mainly SW Asia, some farther W.
A. r. dauricus H. C. Johansen, 1952 - breeds Transbaikalia and Yakutia E to Sea of Okhotsk and S to N Mongolia, Manchuria and NE China (NW Heilong-Jiang); winters S Asia.
A. r. centralasiae (Kistiakovsky, 1928) - breeds E Kazakhstan (Zaysan Basin, E Tien Shan) E to W & S Mongolia, S to N China (Xinjiang, Qinghai, Gansu, probably also Nei Mongol); winters S Asia.
A. r. ussuriensis H. C. Johansen, 1952 - breeds SE Russia (lower Amur area, Ussuriland) S to E China (S to Sichuan and R Yangtze), probably also Korea; winters SE Asia.
A. r. sinensis (Bonaparte, 1850) - SE China S of R Yangtze.

Descriptive notes. 17-18 cm; 21-40 g. Large pipit with long, stout legs, long toes, very long hind claw. Nominate race has long creamy to buff supercilium tapering at rear, pale cream-buff eyering and lores, occasionally darkish loral stripe; prominent dark malar stripe and patch, pale buff-brown patch on rear cheek; above, buff-brown to dun-brown, streaked blackish, lower back and rump less streaked; primaries, secondaries and primary coverts dark brown with narrow white edges, tertials and secondary wing-coverts tipped and edged rufous or buff, greater coverts paler with broad sandy-buff edges and tips, median coverts blackish-centred with broad buffish-white margins, lesser coverts sandy brown; tail blackish-brown, edges of T1 tinged rufous with broad buff-brown edging, T5 and T6 with outer web and much of distal inner web white; upper throat white, lower throat, breast and flanks deep buff, belly white, band of fine blackish streaks across breast and upper flanks; underwing-coverts and axillaries creamy buff to buff-grey; iris dark brown; upper mandible dark grey, lower mandible pale pink, sometimes yellowish; legs and toes pale pink or yellowish-pink, hind claw (14-22 mm) longer than hind toe. Sexes alike. Juvenile has unmarked pale lores, pale feather edges on upperparts giving scaly effect, two indistinct pale wingbars, is more sharply streaked below; pale edgings lost by first winter. Race *centralasiae* is paler than nominate, has less contrasting streaks on upperparts, yellower underparts; *dauricus* is similar to previous, but has less stout legs and shorter hind claw than nominate; *ussuriensis* is darker, greyer, and with darker streaks than last, is rather small, with relatively longer hind claw; *sinensis* is smallest, with relatively short tail and hind claw, breast and flanks more deeply tinged rufous, fainter streaks on mantle than previous. Voice. Song, usually in flight, "chewee-chewee-chewee" with much individual variation, 3-12 notes. Call a loud, harsh explosive "r-rump" or "schreep".
Habitat. Any open country, steppe grassland, paddyfields, stubble fields and cultivations, edges of reservoirs and marshy areas. Usually below 1800 m; in Himalayas, recorded on passage to 6300 m on Mt Everest.
Food and Feeding. Mainly adult and larval insects, notably beetles (Coleoptera) and grasshoppers (Orthoptera). Of 48 samples obtained in studies using neck-collars, 93·7% contained grasshoppers, 8% beetles, 6% hymenopterans, 6% spiders (Araneae). Of 149 items in further samples, 24% were caterpillars (Lepidoptera), 19·5% flies (Diptera), 16% beetles, 15% hymenopteran adults and larvae, 12% dragonflies (Odonata), 5% spiders, just over 1% each stoneflies (Plecoptera) and worms (Annelida), and less than 1% lacewings (Neuroptera) and homopteran bugs. In winter in Europe, a butterfly, an ichneumon wasp (Hymenoptera), a ladybird (Coccinellidae) and seed mix were eaten. Forages on the ground, picking terrestrial invertebrates. May associate with grazing livestock.
Breeding. Mainly Apr-Jul. Sings in descending display-flight. Nest a large cup of coarse grass and roots, lined with finer material such as grasses and hair, built on ground among grass tufts, often in a depression. Clutch 3-4 eggs, usually 3 in S of range; incubation and brood-feeding by both sexes, periods not documented.
Movements. Long-distance migrant; winters mostly in S parts of Asia E to Philippines and W New Guinea, and S to Sundas. Race *sinensis* probably remains mostly within SE China. Nominate race migrates mainly to Indian Subcontinent, but regular winterer also in S Europe (Atlantic coast, Mediterranean region), NW Africa and Middle East; peak numbers in latter regions in Dec-Feb, e.g. flocks of up to 29 in Spain, 33 in Italy (Sardinia) and 15 in Morocco; in Israel also regular passage migrant, with up to 420 recorded in autumn (mid-Sept to Dec), fewer in spring, suggesting that some migrate to E Africa. Observations in W Africa (Mali and around L Chad) also suggest possible wintering in that region. In addition, nominate race recorded as vagrant in most countries of W Europe, well to W of main breeding and wintering range. Some migrants of E races may reach N Australia.
Status and Conservation. Not globally threatened. Common throughout most of range; no evidence for any decline.

3. Paddyfield Pipit

Anthus rufulus

French: Pipit rousset **German**: Orientspornpieper **Spanish**: Bisbita Oriental
Other common names: Indian/Oriental Pipit

Taxonomy. *Anthus rufulus* Vieillot, 1818, Bengal, India.
May form a superspecies with *A. novaeseelandiae*, *A. richardi* and *A. cinnamomeus*, and all were formerly treated as conspecific; recent DNA studies, however, do not support a close relationship between them. Race *albidus* possibly indistinguishable from *medius*; also, birds from Lombok and Sumbawa (W Lesser Sundas) somewhat intermediate between former race and *malayensis*. N Sulawesi population of uncertain racial identity, tentatively included in *albidus*. Six subspecies recognized.
Subspecies and Distribution.
A. r. waitei Whistler, 1936 - NW Indian Subcontinent.
A. r. rufulus Vieillot, 1818 - most of Indian Subcontinent (except NW, N and extreme SW) E to S China, S to S Thailand and Indochina.
A. r. malayensis Eyton, 1839 - extreme SW India (Nilgiri Hills), Sri Lanka, Malay Peninsula, Sumatra, Java, N & SE Borneo and S Indochina.
A. r. lugubris (Walden, 1875) - Philippines; possibly also N Borneo.
A. r. albidus Stresemann, 1912 - Sulawesi, Bali and W Lesser Sundas (Lombok, Sumbawa, Komodo, Padar, Rinca, Flores, Sumba).
A. r. medius Wallace, 1864 - E Lesser Sundas (Sawu, Roti, Timor, Kisar, Leti, Moa, Sermata).

Descriptive notes. 15-16 cm; 17·4-22·7 g. Nominate race has long creamy to buff supercilium tapering at rear, pale lores (occasionally darkish loral stripe), dark submoustachial stripe, prominent dark malar stripe and patch; above, greyish-brown, streaked blackish, less streaked on back and rump; primaries, secondaries and primary coverts dark brown with narrow white edges, tertials and secondary wing-coverts tipped and edged rufous, greater coverts paler with broad sandy-buff edges and tips, median coverts with blackish centres and broad buff-white tips (forming wingbar), lesser coverts sandy brown; tail blackish-brown, edges of T1 tinged rufous, T5 and T6 with outer web and much of distal inner web white; upper throat white, lower throat, breast and flanks deep buff, belly white, band of fine blackish streaks across breast; underwing-coverts and axillaries creamy buff; iris dark brown; upper mandible dark grey, lower mandible pale pink, sometimes yellowish; legs pale pink or yellowish-pink, long hind claw (10-14 mm). Differs from very similar *A. richardi* in shorter legs, generally paler, greyer and less heavily streaked plumage, median coverts with dark centres more square-cut (less pointed) and margins paler and narrower. Sexes alike. Juvenile has unmarked pale lores, pale tawny feather edges on upperparts giving scaly effect, two indistinct pale wingbars, is more sharply streaked below; pale edgings lost by first winter. Race *waitei* is paler grey and less heavily streaked than nominate; *malayensis* is darkest, most heavily streaked; *albidus* is small, greyish above, whitish below; *medius* is like last but more buffy above, more ochraceous and less white below; *lugubris* has upperparts light buffy brown, streaked dark brown, underparts buffy white. Voice. Song, in flight, includes a wheezy trill or series of feeble "tseep" notes, on average higher-pitched and faster than those of *A. richardi*, with series of 5-20 "clink" notes during descent. Call a harsh explosive "chwist", or thin high-pitched "pipit" or "tseep tseep" or "chep", often repeated; alarm call at nest a feeble "tsip tsip tsip".
Habitat. Open country, short grassland, paddyfields, stubble fields and cultivations, also airfields, roadsides, wetland edges, savanna woodland. To 1000 m, exceptionally to 3000 m, in Pakistan and NW India (race *waitei*); *malayensis* occurs to 2100 m in Sri Lanka and to 1500 m in Sumatra, and in SW India (Nilgiri Hills) is largely replaced by *A. nilghiriensis* above 1800 m (some overlap). From sea-level to 2400 m in Wallacea.
Food and Feeding. Mainly adult and larval insects. Stomach contents included weevils (Curculionidae), ants (Hymenoptera), termites (Isoptera), bugs (Hemiptera), also spiders (Araneae); also weed seeds and vegetable matter. Forages on the ground, picking terrestrial invertebrates. Singly or in pairs, occasionally small groups.
Breeding. Mar-Jul, occasionally to Sept, in N Indian Subcontinent; mostly in Nov-Jun dry season elsewhere, in Sri Lanka Jan-Jul (peak Apr/May); lays in Apr-Jun in Sumatra, and breeds in Apr-Jun on Lombok, Sumbawa and Flores; birds with enlarged gonads in Oct in S Sulawesi; normally single-brooded. In song flight ascends in series of curves, before diving to the ground. Nest built by female as male keeps guard (*malayensis*), or by both sexes (nominate), a typical cup of grass and roots, lined with finer material, placed on ground among grass tufts, and often in depression (e.g. cattle footprint); may be partly domed, and have tunnel entrance 30-60 cm long. Clutch 3-4 eggs, usually 3 in S; incubation and brood-feeding by both sexes, incubation and fledging periods not documented; injury-feigning display reported. Nests parasitized by Common Cuckoo (*Cuculus canorus*).
Movements. Resident; some local and altitudinal movements. A summer visitor in the Himalayan foothills (race *waitei*).
Status and Conservation. Not globally threatened. Common throughout most of range; generally uncommon, locally more common, in Wallacea. No evidence for any decline in any region.

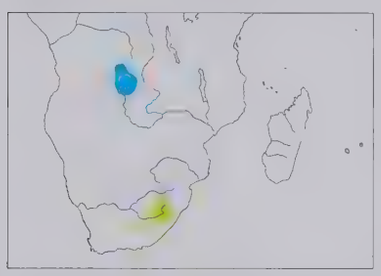
4. Grassveld Pipit

Anthus cinnamomeus

French: Pipit africain **German**: Zimtspornpieper **Spanish**: Bisbita Africano
Other common names: African/Grassland Pipit; Cameroon Pipit (*camaroonensis*)

Taxonomy. *Anthus cinnamomeus* Rüppell, 1840, Simien Mountains, north Ethiopia.
May form a superspecies with *A. novaeseelandiae*, *A. richardi* and *A. rufulus*, and all were formerly treated as conspecific; recent DNA studies, however, do not support a close relationship between them. Some research suggests that present species is more closely related to *A. similis*. Has been considered to include *A. latistriatus* as a race; conversely, *winterbottomi* sometimes treated as a race of latter or of *A. similis*, and has been synonymized with nominate race of *A. nyassae* by some authors. Race *camaroonensis* sometimes considered a separate species; described race *katangae* (from L Musole, in SE DRCongo) merged with *lichenya*. Fourteen subspecies recognized.
Subspecies and Distribution.
A. c. lynesi Bannerman & Bates, 1926 - SE Nigeria, Cameroon, W Chad and W Sudan.
A. c. camaroonensis Shelley, 1900 - W Cameroon (Mt Manenguba, Mt Cameroon).
A. c. stabilis Clancey, 1986 - C & SE Sudan.
A. c. cinnamomeus Rüppell, 1840 - W & SE Ethiopian Highlands.
A. c. eximius Clancey, 1986 - SW Arabia.
A. c. annae Meinertzhagen, 1921 - Eritrea, Djibouti, Somalia, SE Kenya and NE Tanzania.
A. c. itombwensis Prigogine, 1982 - highlands of E DRCongo.
A. c. lacuum Meinertzhagen, 1920 - SE Uganda, W & S Kenya and N & C Tanzania.
A. c. winterbottomi Clancey, 1985 - highlands of NE Zambia, N Malawi, S Tanzania and NW Mozambique.
A. c. lichenya Vincent, 1933 - NE Angola, S & E DRCongo, and from W Uganda S to N & E Zambia, C Malawi, adjacent NW Mozambique, and Zimbabwe plateau.
A. c. spurium Clancey, 1951 - SE Tanzania S to NE Namibia, Zambezi Valley and coastal lowlands of Mozambique.
A. c. bocagei Nicholson, 1884 - W & S Angola S to NW South Africa (Northern Cape).
A. c. grotei Niethammer, 1957 - N Namibia and N Botswana.
A. c. rufuloides Roberts, 1936 - South Africa (except NW), Swaziland and Lesotho lowlands.

Descriptive notes. 16-17 cm; 18-31g. Large, slim, long-legged and long-tailed, well-marked pipit. Nominate race has buff lores and broad supercilium, dark brown eyestripe, buffish ear-coverts with dark brown streaks, blackish malar stripe; upperparts rich cinnamon with strong blackish streaking, back and rump almost uniform; wing feathers black or blackish-brown, edged and tipped rich cinnamon, lesser wing-coverts buff-brown; tail dark brown, T5 with much white on outer web, T6 with outer web and much of inner web buff-tinged white; underparts buff or tawny, paler on throat and centre of belly, deeper buff on breast and flanks, distinct short blackish streaks on upper breast; underwing-coverts and axillaries buff; iris dark brown; bill blackish-brown, yellowish base of lower mandible; legs pinkish-flesh, hind claw longer than hind toe. Distinguished from *A. similis*, *A. nyassae* and *A. hoeschi* by slightly smaller size, smaller bill, somewhat paler plumage, whiter colour on outer tail feathers. Sexes alike. Juvenile is more heavily streaked dorsally, has sharp white edges of tertials and greater and median coverts, pink base of bill. Racial differences mostly slight: *lynesi* is larger than other races, darker than most, with heavier, blacker streaking above, contrasting cinnamon-buff edgings of wing feathers, deeper cinnamon-buff below, broader larger black streaks confined to upper breast; *camaroonensis* resembles last but is less cinnamon, more buff, below, with pale buff edgings of wing feathers; *annae* is paler and greyer above than nominate; *eximius* is more richly coloured than last; *itombwensis* is very dark above, with heavy blackish streaking on crown and mantle, buff below, heavy streaks extending to mid-breast and flanks; *winterbottomi* has throat and belly white, rest of underparts vinous buff, whiter tips of outer tail feathers; *lacuum* is duller, more olive-brown, than nominate, also paler below, with shorter, more sparse streaks on breast; *spurium* is colder and greyer than previous, with blacker breast streaking; *stabilis* is more buffish, with more pronounced streaking on crown and mantle, heavier blacker streaks below extending to lower breast; *lichenya* is warm dark brown above, heavily streaked, rich buff with sharper, more extensive streaking below, has little or no white on T5; *bocagei* is paler and more sandy above, rather pale with few streaks below; *grotei* is paler and greyer than previous; *rufuloides* is buffish-brown and less strongly streaked above, less buff below, with browner, more obvious breast streaking than nominate. Voice. Song, from perch or in flight, brief, of simple repeated notes, "tree-tree-tree" or "sreet-sreet-sreet-sreet". Calls include single "tweep" or disyllabic "tsseep tseep", also sharp "chip" or "trip" when flushed, and loud, sharp "psiu" in flight.
Habitat. Grassland, including fallow fields and other agricultural land, edges of pans, also recently burnt areas; also open areas in towns and villages. Breeds from sea-level to over 3400 m.
Food and Feeding. Small invertebrates, also seeds and other vegetable matter. In one study, grasshoppers (Acrididae) and beetles (Coleoptera) found in 69% of 51 stomachs, with moths and butterflies (Lepidoptera), ants (Hymenoptera), bugs (Hemiptera) and termites (Isoptera) also important prey. Stomach analyses in South Africa showed beetles, especially weevils (Curculionidae), and insect larvae, mainly of coleopterans and lepidopterans, to be main prey. Flies and their larvae (Diptera), dragonflies (Odonata), larval dung beetles (Scarabaeidae), mantids, cockroaches (Blattodea), spiders (Araneae), millipedes (Diplopoda) and other small invertebrates, such as earthworms (Oligochaeta), are also eaten, as well as weed seeds and other vegetable matter. Feathers and grit also ingested. Forages mainly on the ground or from low perches; walks or runs to pick prey, sometimes jumps or flies up to catch winged insect. Gregarious, often in groups, and in flocks of up to 100 in non-breeding season.
Breeding. Mainly before or during rains: breeds in Feb-Apr in Cameroon Highlands, Apr in Ethiopia, May-Jun in Uganda, Mar-Jul and Nov-Dec in Kenya, Mar-May, Sept and Oct in S Tanzania,



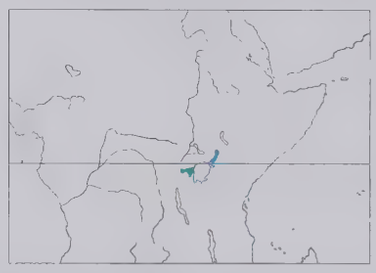
Aug-Oct in Zambia, Sept-Nov in Zimbabwe, Aug-Mar elsewhere in S Africa. Monogamous; territorial. Display has short song flight ending in steep dive. Nest a shallow cup of coarse dry grass, lined with rootlets, fibre and hair, built in depression in ground, usually concealed at base of a grass tussock, rock or shrub. Clutch 2-4 eggs, usually 3; incubation by both sexes, mainly by female, period 12-13 days; chicks fed by both parents, nestling period 12-17 days.
Movements. S populations mostly migratory, move N & E to as far as Zimbabwe, Zambia, Mozambique and possibly Malawi in non-breeding season. Other populations largely sedentary, although some local movements probable; those breeding at higher elevations, e.g. *winterbottomi*, make altitudinal movements. Apparently resident in W Africa; recorded in non-breeding season in S Mauritania and from Liberia and C Mali E to Chad, but race or races involved uncertain.
Status and Conservation. Not globally threatened. Common and widespread throughout most of range; rare in Arabia. Pipits occurring commonly around L Chad and in Mali in non-breeding season of uncertain identity, thought to be either of this species or, possibly, migrants of *A. richardi*; further study required. Benefits from clearance of savanna and woodland for agriculture, with fallow fields and arable land providing suitable wintering/feeding areas. Intensive agriculture, involving use of pesticides, may be a local threat.
Bibliography. Archer & Godman (1937-1961), Bannerman (1953), Benson (1946a), Benson & Benson (1977), Borrett (1969a), Borrett & Wilson (1971a), Campbell (1989), Chapin (1953), Clancey (1954, 1964b, 1968b, 1977b, 1984a, 1986a, 1986e, 1990a), Dean (1987, 2000), Dowsett & Dowsett-Lemaire (1997), Dowsett-Lemaire (1989), Edwards (1999), Gibbon (1989a), Ginn *et al.* (1989), Hall (1961), Hall & Moreau (1970), Harris *et al.* (1992), Keith *et al.* (1992), Kopij *et al.* (2002), Lewis & Pomeroy (1989), Louette (1981), Mackworth-Praed & Grant (1960, 1963), Maclean (1993a), McDonald (1974), Mendelsohn (1984a, 1984b), Pakenham (1979), Parker (1990, 1999), Paterson (1959), Pedersen (2000), Penry (1994), Prigogine (1982), Rossouw (1987), Saunders (1989), Short *et al.* (1990), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Skead (1975), Stevenson & Fanshawe (2002), Steyn (1970, 1996), Tait (1991), Tarboton (2001), Tree (1963a, 1965), Voelker (1999a, 1999b, 1999c), Voelker & Edwards (1998), Wilson (1988), Winterbottom (1960), Woodall (1975), Zimmerman *et al.* (1996).

5. Mountain Pipit

Anthus hoeschi

French: Pipit alticole **German**: Hoeschspornpieper **Spanish**: Bisbita Montano

Taxonomy. *Anthus hoeschi* Stresemann, 1938, Erongo Mountains, Damaraland, Namibia.
Recent studies suggest that it is most closely linked phylogenetically to *A. latistriatus*. Formerly treated as part of expanded "*A. novaeseelandiae* complex", and synonymized with race *bocagei* of *A. cinnamomeus* by some authors. Described races *editus* (from Lesotho) and *lwenarum* (from NW Zambia) considered indistinguishable from other populations. Monotypic.
Distribution. Breeds in the Drakensberg of South Africa (KwaZulu-Natal, N Eastern Cape) and Lesotho; migrates to E Angola, S DRCongo and NW Zambia.



Descriptive notes. 18·5 cm; 23·5-31 g. Has broad buffy supercilium, dark brown eyestripe and moustachial stripe, narrow blackish malar streak; above, brown with heavy black streaking, rump less streaked; wing feathers blackish-brown, edged and tipped buff, lesser coverts buff; tail blackish-brown, T5 tipped buffish-white, T6 mostly buffish-white; pale buff below, whiter on throat, prominent short blackish-brown streaks on upper breast; axillaries and underwing-coverts buff; iris dark brown; bill dark brown, base of lower mandible pinkish or flesh-coloured; legs orange-brown. Distinguished from *A. similis* and *A. cinnamomeus* by darker coloration, heavier blackish-brown streaks on crown and mantle, more heavily dark-spotted upper breast, longer wing and tail, buffy white (not white) on two outer tail feathers, pinkish or flesh-coloured (rather than yellow) base of bill. Sexes alike. Juvenile not described. Voice. Song, given in flight or from perch, rendered as "tchrit-chritchritchri", "tsi-plu-tsi-plu-tsi-plu" or lower-pitched "chiri-chiri-chiri-chiri", deeper and more varied than that of *A. cinnamomeus*. Call a disyllabic "tuchit tuchit", flight call "psiu" or "chiri"; alarm call near nest a slowly repeated "twit".
Habitat. Short montane grassland at 2000-2700 m during breeding season; largely segregated from *A. cinnamomeus* by altitude, although the two apparently co-exist on the high plateau of Naudesk in the Drakensberg. On migration occurs on any grassland, but thought to winter on damp grassland in the Zambezi-Congo watershed.
Food and Feeding. Little known. Appears to forage mainly on the ground, picking at small invertebrates, as other members of genus.
Breeding. Laying recorded from late Nov to early Jan. Monogamous; territorial. Cruising display-flight. Nest a grass cup, placed on ground under a clump of grass. Clutch 3-4 eggs; incubation and fledging periods unknown.
Movements. Migratory. After breeding, moves N to E Angola, S DRCongo and NW Zambia; possibly also to N Angola. Details poorly known; dates of museum specimens indicate that it probably moves N through Northern Cape, where observed in Kimberley area Feb-Apr, and through Botswana and Namibia; may return S via E Botswana, where four specimens in Sept/Oct; present on breeding grounds from late Oct or Nov. Status in Zimbabwe uncertain, with only three specimens of doubtful status.
Status and Conservation. Not globally threatened. Restricted-range species: present in Lesotho Highlands EBA. No population estimates available; apparently rare. No evidence for any decrease in numbers. Nevertheless, small population within small range, and requirement for short montane grassland, could render it potentially vulnerable. Little known outside breeding range.
Bibliography. 6. Jackson's Pipit

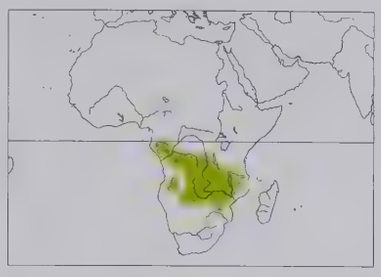
Anthus latistriatus

French: Pipit à raies larges **German**: Jacksonpieper **Spanish**: Bisbita de Jackson

Taxonomy. *Anthus latistriatus* Jackson, 1899, Kavirondo, south-western Kenya.
Formerly considered conspecific with *A. similis*, but has different wing formula. Alternatively, often regarded as a melanistic form of *A. cinnamomeus*, and race *winterbottomi* of latter placed with present species by some authors; differs, however, vocally and in hind-claw morphology. Sometimes treated as a race of expanded *A. novaeseelandiae*. Monotypic.
Distribution. Breeding range uncertain, believed to be Itombwe Highlands, in E DRCongo. SW Uganda, NW Tanzania and W Kenya in non-breeding season.

Descriptive notes. 18·5 cm. Has pale creamy supercilium, thin dark eyestripe and moustachial stripe, pale submoustachial stripe, narrow blackish malar stripe; blackish-brown upperparts with paler brown feather edgings, giving heavily streaked appearance; upperwing-coverts and tertials edged rich buff; tail blackish-brown, T5 pale brown with greyish-buff spot on tip, T6 greyish-buff or pale brown; throat and centre of upper breast pale buffy white, rest of underparts buffish-brown or rich cinnamon-buff, breast with heavy black streaks, sparse streaks on upper belly, blackish-brown streaks on flanks and thighs; iris brown; bill darkish brown, base of lower mandible pinkish-grey; legs pale brown, hind claw relatively short (8 mm). Distinguished from all races of *A. cinnamomeus* by darker plumage above and below, pinkish (not yellow) base of lower mandible, shorter and straighter hind claw. Sexes alike. Juvenile is more strongly mottled above and on breast. Voice. Song described as rapid "tit-it-it-it-it-it-it" followed by less harsh "trit-rit-rit-rit-rit". Call "chrit".
Habitat. Thought to breed on alpine grassland plateaux, at up to 2400 m; at lower altitudes at other times.
Food and Feeding. No information.
Breeding. Not known.
Movements. Believed to descend to lower altitudes after breeding.
Status and Conservation. Not globally threatened. Very poorly known species. No information on numbers, and knowledge of distribution incomplete; very rare in W Kenya. Ecology and breeding biology not recorded.
Bibliography. Chapin (1953), Clancey (1984a, 1985a, 1985b, 1986c, 1989b, 1990a), Dowsett & Dowsett-Lemaire (1987), Mackworth-Praed & Grant (1960, 1963), Newman *et al.* (1992), Prigogine (1982), Sinclair & Ryan (2003).

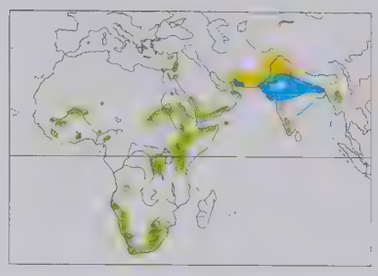


7. Woodland Pipit

Anthus nyassae

French: Pipit forestier **German**: Waldlandpieper **Spanish**: Bisbita del Nyasa
Other common names: Brachystegia/Wood Pipit; Chapin's Pipit (*schoutedeni*)

Taxonomy. *Anthus nicholsoni nyassae* Neumann, 1906, between Sangesi and Songea, south Tanzania.
Previously regarded as conspecific with *A. similis*. Race *winterbottomi* of *A. cinnamomeus* has been treated by some authors as a synonym of nominate race of present species. Race *chersophilus* possibly inseparable from *schoutedeni*, and both possibly better merged with nominate. Four subspecies recognized.
Subspecies and Distribution.
A. n. schoutedeni Chapin, 1937 - SE Gabon and S PRCongo E to S DRCongo, S to SC & SE Angola.
A. n. nyassae Neumann, 1906 - Zambia, SW & SE Tanzania, Malawi and NW Mozambique.
A. n. chersophilus Clancey, 1989 - NE Namibia and N Botswana.
A. n. frondicolus Clancey, 1964 - Zimbabwe and adjacent S Mozambique.
Descriptive notes. 18 cm; 23·8-25·9 g. Fairly large pipit with rather upright posture. Nominate race has prominent whitish supercilium and submoustachial stripe, thin dark malar stripe; above, rich warm brown with blackish streaks; wing feathers blackish-brown, edged light rufous-buff; tail dark brown, T5 with wedge of variable size on inner web white or buff-white, T6 with outer web and large distal wedge on inner web white; throat whitish, underparts vinous buff, streaked blackish on breast; iris dark brown; bill dark horn, pale pinkish base of lower mandible; legs flesh-brown. Differs from closely similar *A. similis* in whiter supercilium, more distinct streaking above. Sexes alike. Juvenile is darker above, with scalloped appearance, has well-defined dark spots, rather than streaks, on breast. Race *frondicolus* is rather cold above, with more prominent streaking than nominate; *chersophilus* is less saturated dorsally than previous, with whiter supercilium, paler wings, pale areas of outer rectrix whiter, breast light vinaceous, not buff, with more diffuse streaking, rest of underside white; *schoutedeni* is also prominently streaked above, throat and belly white, breast streaking sharp. Voice. Song, often from treetop, consists of short phrases, repeated, with modulations, at one-second intervals, "tssirit, tseu, sreep, tyoop" etc. Diagnostic high tremolo call usually given as it flies off.



Habitat. Broadleaf woodland savanna with lightly grassed understorey; especially miombo (*Brachystegia- Julbernardia*) woodland in Zimbabwe, and *Burkea-Baikiaea* and *Pterocarpus* woodland in Namibia and Botswana. Lowlands to above 1800 m.
Food and Feeding. Small invertebrates, also some seeds. Stomach contents have included grasshoppers and crickets (Orthoptera), mantids, cockroaches (of genus *Blattaria*), bugs (Hemiptera), beetles (including scarabaeids and *Cicindela* tiger beetles), both worker and soldier termites (including *Hodotermes* harvester termites and *Macroterma* species), noctuid moths, ants (Hymenoptera) and braconid and sphecoid wasps, and spiders (Araneae). Forages on ground under trees and in open clearings; also gleans insects from leaves in trees.
Breeding. Little known. Lays before and during rains, but in dry season in miombo: Jan, Feb and Jul-Nov (mostly Sept-Nov) in Zimbabwe, and Sept-Nov in Malawi and Zambia. Nest a grass cup, lined with fine split grass and wood fibre. Clutch 2-3 eggs; incubation and fledging periods unknown.
Movements. Believed to be sedentary.
Status and Conservation. Not globally threatened. Current status uncertain. Has been suggested that further destruction of miombo and other broadleaf woodlands could place this species at risk.
Bibliography. Benson & Benson (1977), Benson *et al.* (1971), Brewster & Major (2000), Borrow & Demey (2001), Brown (1990, 1993), Chapin (1953), Clancey (1985a, 1987b, 1988, 1989b, 1990a, 1993b, 1996), Finch (2002), Harrison *et al.* (1997), Harwin *et al.* (1994), Hustler (1993), Irwin (1981), Keith *et al.* (1992), Lynes (1934), Mackworth-Praed & Grant (1960, 1963, 1973), Newman *et al.* (1992), Pedersen (2000), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Stjernstedt (2003, 2004), Tarboton (2001).

8. Long-billed Pipit

Anthus similis

French: Pipit à long bec **German**: Langschnabelpieper **Spanish**: Bisbita Piquilargo
Other common names: Brown Rock Pipit; Bannerman's Pipit (*bannermani*); Indian Rock Pipit (*jerdoni*); Indian Long-billed Pipit, Rufous Rock Pipit (*similis*); Kerala Rock Pipit (*travancoriensis*); Moco Pipit ("*moco*"); Persian Rock Pipit (*decaptus*)

Taxonomy. *Anthus similis* Jerdon, 1840, Jalna, Nilgiri Hills, southern India.
Has been thought to form a superspecies with *A. campestris*. Previously regarded as conspecific with *A. nyassae*. Race *winterbottomi* of *A. cinnamomeus* has sometimes been treated as a race of present species. Race *bannermani* considered a separate species, possibly closer to *A. latistriatus*, by some authors. Taxonomy complex, and listed ranges somewhat tentative; revision required. Race *nivescens* is possibly inseparable from *arabicus*, and *primarius* is sometimes merged with *nicholsoni*. Other described races are *josensis* (from C Nigeria) and *chapini* (Cameroon), both included within *bannermani*; *neumannianus* (Ethiopia) and *chyuluensis* (Chyulu Hills, in Kenya), included in *hararensis*; *moco* (WC Angola) and *hallae* (Uganda), inseparable from *dewittei*; and *cockburniae* (Nilgiris), synonymous with nominate. Nineteen subspecies recognized.
Subspecies and Distribution.
A. s. asbenaicus Rothschild, 1920 - S Sahara in C & E Mali and C Niger.
A. s. bannermani Bates, 1930 - mountains of SW Mali, Guinea, Sierra Leone and N Liberia E to C & SE Nigeria and W Cameroon.
A. s. captus Hartert, 1905 - Lebanon, Syria, Israel, Palestine and W Jordan.
A. s. jebelmarrae Lynes, 1920 - mountains of W & C Sudan.
A. s. nivescens Reichenow, 1905 - mountains of SE Egypt (Gebel Elba), and from hills of Red Sea coast in NE Sudan and Eritrea S to mountains in NW Somalia and N Kenya.
A. s. hararensis Neumann, 1906 - highlands of Eritrea, Ethiopia, Kenya and Tanzania.
A. s. dewittei Chapin, 1937 - highlands of E & SE DRCongo, SW Uganda, Rwanda, Burundi and C Angola (Mt Moco, in Huambo).
A. s. palliditinctus Clancey, 1956 - extreme SW Angola and NW Namibia.
A. s. leucocraspedon Reichenow, 1915 - W & S Namibia and SW South Africa (W Northern Cape, NW Western Cape).
A. s. nicholsoni Sharpe, 1884 - SE Botswana and NE South Africa (Northern Province S to Free State).
A. s. petricolus Clancey, 1956 - Lesotho and E South Africa.
A. s. primarius Clancey, 1990 - S South Africa (S Western Cape E to N Eastern Cape).
A. s. arabicus Hartert, 1917 - SW, S & SE Arabian Peninsula.
A. s. sokotrae Hartert, 1917 - Socotra I.
A. s. decaptus Meinertzhagen, 1920 - S Iran (Zagros Mts) E to W Pakistan (Baluchistan); winters S to NW India.
A. s. jerdoni Finsch, 1870 - breeds E Afghanistan E in Himalayas to W Nepal; winters S to NC India and Bangladesh.
A. s. similis Jerdon, 1840 - peninsular India from Bombay S to Karnataka and W Tamil Nadu (Nilgiri and Palni Hills).
A. s. travancoriensis Ripley, 1953 - SW India (Kerala-W Tamil Nadu border, from Palni Hills S to Ashambu Hills).
A. s. yamethini B. P. Hall, 1957 - C Myanmar.
Descriptive notes. 17-20 cm; male 30-35 g, female 28-31 g, unsexed (*hararensis*) 21·5-29 g, unsexed (*nicholsoni*) 22-25 g. Large, stout pipit with variably streaked upperparts and breast, unstreaked flanks. Nominate race has prominent buff supercilium, buff-streaked brown lores and ear-coverts, indistinct narrow dark brown malar stripe; crown and upperparts dark grey-brown, distinctly streaked blackish-brown; wing feathers dark brown, tipped and edged buff, lesser wing-coverts buffish-brown; tail dark brown, T5 with buffish-white outer edges and tip of inner web, T6 with buffy outer web and large dusky rufous distal wedge on inner web; throat greyish-white, underparts dark pinkish-rufous, breast clearly streaked grey-brown, longest undertail-coverts with dark centres; underwing-coverts and axillaries warm buff; iris dark brown; bill dark horn, pale pinkish base of lower mandible; legs flesh-brown, hind claw shorter than hind toe. Differs from e.g. "*A. novaeseelandiae* complex" in slightly larger size, proportionately larger bill, darker upperparts, buff (not white) outer tail feathers. Sexes alike. Juvenile is darker than adult, with more obvious streaking above, giving scalloped appearance, pale wingbars more obvious, paler below, breast with well-defined spots, rather than streaks. Races vary in size, leg length, plumage coloration and pattern, more streaked above in Afrotropics and Arabia, generally unstreaked in N & NE of range: *bannermani* is very dark earth-brown with sandy-buff fringes above, sandy-buff with heavy streaks below, distinct malar stripe; *asbenaicus* is like previous but less dark, also less streaked below; *jebelmarrae* has paler and warmer upperparts, greyish tinge on hindneck, buff with cinnamon wash below, poorly defined chest streaks; *hararensis* is darker, greyer and colder above, with more distinct streaking, feather edges narrow and lighter, cinnamon-buff below with dusky streaks; *dewittei* is smaller and darker than previous; *nivescens* is relatively pale above, rather pale cinnamon-buff below, malar stripe well marked; *sokotrae* resembles last but is greyer and more distinctly marked, with well-defined dark centres and light edges of feathers on upperparts (looking more clearly streaked); *nicholsoni* is brown above with indistinct streaks, most prominent on head, has warm buff underparts; *petricolus* is darker and colder than last, also less buffy; *primarius* is similar to previous, but with breast streaking more extensive, and blacker malar streak, crown feathers and breast streaking; *leucocraspedon* is paler, more sandy, with pale buff underparts, short fine breast streaks; *palliditinctus* is greyer above and paler below than previous; *captus* is small, relatively short-legged, greyish and indistinctly streaked above, more pale pinkish-buff below, darker on flanks and undertail-coverts, brown-grey streaks form diffuse breastband, central pair of tail feathers with pale edges, outer two pairs with pale buffish or greyish wedges; *arabicus* is slightly larger and darker than last, browner and with broader and darker streaks above, more dusky rufous and with more numerous and darker streaks below; *decaptus* is larger than previous, has proportionately longer tail, shorter heavier bill, mantle and scapulars almost plain, rufous underparts paler and less streaked; *jerdoni* is smaller and darker than last, more brownish with very little streaking above, more rufous below with more breast streaking, supercilium and ear-coverts more rufous, also pale wedges on outer tail more buffy; *travancoriensis* is more uniformly dark above and below than nominate, has cinnamon (not buff) underparts, also edges of outer rectrix darker tawny-olive, inner web of T5 with much larger area of dark brown; *yamethini* is small, with proportionately short tail, breast streaks rather indistinct. VOICE. Song, from ground or in flight, a simple unmusical series of high, monotonous and well-spaced, often disjointed notes and phrases, e.g. "tjup threee tjup tjup threee" or "chreep shreep chew-ee", more varied than that of *A. vaalensis* or *A. leucophrys*. Call sharp "wheet" or loud, ringing "che-vlee".

Habitat. Stony or rocky hillsides with sparse ground cover, often with scrub or open woodland. In Africa, often slopes in rather arid and eroded broken veld, often steppe-like, with erosion scars, stones and rocks interspersed with grass clumps and low scrub, trees and light woodland. Visits nearby well-grazed or burnt ground; often one of the first pipits in S Africa to visit an area after fire. Lowlands to 2600 m; 1300-1800 m in NE Africa.
Food and Feeding. Insects and other small invertebrates, also seeds; grit also ingested. Diet includes grasshoppers and crickets (Orthoptera), beetles (Coleoptera), bugs (Hemiptera), mantids (Mantidae), cockroaches (Blattodea), termites (Isoptera), ants and wasps (Hymenoptera), larval and adult moths (Lepidoptera) and spiders (Araneae). Stomach analyses in South Africa revealed mostly beetles, notably weevils (Curculionidae), and insect larvae (mainly coleopterans and lepidopterans), similar to prey taken by *A. cinnamomeus* and *A. leucophrys*. Forages mainly on the ground; also picks prey items from vegetation and branches. Often feeds on recently burnt ground.
Breeding. Breeds in Mar-Apr in Sierra Leone and Cameroon, Jun-Jul in Niger, May-Oct in Sudan, Apr-May in Kenya, Oct-Apr in N Tanzania, Sept-Nov in Malawi and Zambia, Jan, Feb and Jul-Nov (mostly Sept-Nov) in Zimbabwe, and Oct-Dec in South Africa; in Mar-Jul in Israel; in Apr-Aug in Indian Subcontinent. Monogamous; territorial. Fluttering display-flight. Nest a deep cup of dry grass, lined with finer grasses and rootlets, built on ground, often on a slope, in shelter of rock or grass tussock. Clutch 2-3 eggs, sometimes 4 or 5; incubation by female, period 13-14 days; fledging period c. 13-14 days. Nests often parasitized by Common Cuckoo (*Cuculus canorus*) in Israel.
Movements. Generally resident; some local or elevational movements. In Africa, more sedentary than other pipits, with only local movement, often involving changes in altitude. Elsewhere, most upland or montane populations are resident or make altitudinal movements; total or partial short-distance migrant in Himalayas, where race *decaptus* winters in lower valleys and foothills and *jerdoni* descends to below 900 m in the foothills and into NC & NE India and NW Bangladesh. Resident in C & S India and in Myanmar.
Status and Conservation. Not globally threatened. Widespread and locally frequent over its large range. Estimated 1500-2000 pairs in Israel in 1980s. Apparent range expansion in NE Africa; nine individuals recorded in SE Egypt (Wadi Aideib, in Gebel Elba) in Apr 1997 presumed to be a sign of N extension of breeding range of race *nivescens*. As the species inhabits terrain largely unsuitable for agriculture, such as dry rocky hillsides and semi-desert country, it is unlikely to have suffered much from habitat destruction.

9. Kimberley Pipit

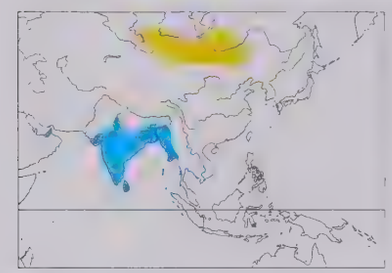
Anthus pseudosimilis

French: Pipit de Kimberley **German**: Kimberleypieper **Spanish**: Bisbita del Kimberley

Taxonomy. *Anthus pseudosimilis* Liversidge and Voelker, 2002, Kimberley, South Africa.

On following pages: 10. Blyth's Pipit (*Anthus godlewskii*); 11. Tawny Pipit (*Anthus campestris*).

Sometimes referred to erroneously as *A. difficilis*. Recently discovered species, separated from *A. similis* by DNA evidence. Molecular-genetic analysis suggests closer relationship with *A. melindae*; possibly also close to *A. leucophrys* or *A. cinnamomeus*. Monotypic.
Distribution. Poorly known. Most records from Kimberley area of C South Africa (E Northern Cape-W Free State); also recorded in NW Northern Cape and E Northern Province, and in S Namibia and on Botswana-South Africa border (Kalagkadi Transfrontier Park).



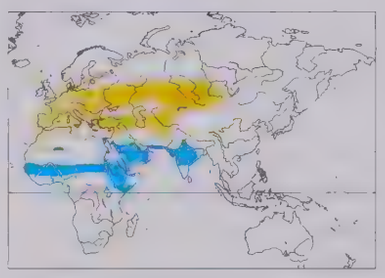
Descriptive notes. 18 cm; 28-35·2 g. Has pale creamy buff supercilium, rufous ear-coverts finely streaked buff, whitish moustachial stripe, blackish-brown malar stripe; crown and upperparts umber-brown with pale feather edgings, giving streaked effect, particularly on crown; wing feathers dark brown, edged buff, pale wing-covert tips forming two indistinct bars; tail dark brown, outer rectrix with outer web and distal half of inner web white, sometimes tinged buffy; pale buff below, slightly darker on breast, which is broadly streaked dark brown; underwing-coverts buff; iris dark brown; bill dark horn, pale yellowish base of lower mandible; legs pale horn. Distinguished from very similar *A. similis* by shorter bill, longer hind claw, and more distinct cream supercilium, rufous ear-coverts and black malar stripe, in the hand also by different wing formula (5th primary shorter than, rather than equal to, 6th) and primary emargination; from similar *A. cinnamomeus* by darker brown streaks on back, more extensive breastband with heavier streaking. Sexes alike. Juvenile undescribed. VOICE. Song, in flight, consists of 3 rather deep notes, "chreep-choop-chreep", in descending series, repeated often; similar to song of *A. similis*, but descending in pitch.
Habitat. Grassland with short vegetation (less than 15 cm tall) and bare ground in open grassveld, open Kalahari sandveld, karroid vegetation, panveld and open pan surroundings, dry riverbeds and limestone areas.
Food and Feeding. Invertebrates; no details. Picks food items from ground and grass while walking in crouched posture. Differs from *A. similis* in frequent tail-flicking and crouching while pecking; unlike that species, does not perch in trees or bushes.
Breeding. Laying Oct-Nov. In display-flight rises to 20-30 m, then calls as it descends in loops. Two nests found: well concealed in grass tufts and roots, one with a tunnel 15 cm long leading to nest cup; one with clutch of 2 eggs, other with brood of 3 chicks.
Movements. Apparently largely sedentary, but variations in numbers at some sites suggest some movements in May-Aug.
Status and Conservation. Not globally threatened. Fairly common within small range. Poorly known species, requires further investigation; records away from Kimberley area suggest that breeding distribution possibly wider than is currently known.
Bibliography. Anon. (2002d), Etherington (2002), Liversidge & Voelker (2002), Sangster (2002), Sinclair & Ryan (2003), Voelker (1999a, 1999b), Voelker & Edwards (1998).

10. Blyth's Pipit

Anthus godlewskii

French: Pipit de Godlewski **German**: Steppenpieper **Spanish**: Bisbita Estepario
Other common names: Godlewski's Pipit

Taxonomy. *Agrodoma godlewskii* Taczanowski, 1876, Argun River valley, Transbaikalia, on Russia-China border.
In the past was sometimes treated as conspecific with *A. campestris*. Monotypic.
Distribution. Breeds from S Russia (E Altai Mts) E to Transbaikalia and NE China (W Heilongjiang), S to S Mongolia and EC Nei Mongol; winters mainly in Indian Subcontinent.



Descriptive notes. 15-17 cm; 17-30·5 g. Has unmarked pale lores, creamy supercilium extending well behind eye, thin blackish moustachial stripe, broad buffy submoustachial stripe, narrow blackish malar stripe and malar patch; above, grey-brown, streaked blackish-brown, wing feathers edged and tipped buffish (two indistinct pale wingbars); tail blackish-brown, edges of central feather pair tinged rufous, outer two pairs edged and tipped buffy and with outer web and much of distal inner web white; buffish below, more orange-buff on flanks, vent and undertail-coverts, pronounced dark streaking on upper breast; axillaries and underwing-coverts orange-buff; iris dark brown; upper mandible darkish grey, lower mandible pale pink with darkish grey tip; legs pale pink or yellowish-pink, hind claw medium length (13 mm) and comparatively weak. Distinguished from *A. richardi* by shorter, more pointed bill, shorter hind claw, more strongly streaked crown and nape, less distinct supercilium, paler underparts, paler tips and more square-shaped dark centres of median wing-coverts; from *A. campestris* by streaked breast. Sexes alike. Juvenile is less extensively dark-streaked, has white feather tips giving scalloped appearance, wingbars whiter and more prominent. VOICE. Song, usually in flight, a series of rasping "zret" notes interspersed with higher "zrit" notes, occasionally brief interjections of more complex rapid phrases, ends with fast repetition of harsh notes, lasts up to 1 minute or more; very different from songs of *A. richardi*, *A. rufulus* and *A. campestris*. Calls include loud, discordant and clipped "chup", "chep" or "choop", usually in flight, and longer "psheeu", usually when flushed; often combined, e.g. "pshee chep-chep".
Habitat. Breeds on dry rocky mountain slopes, usually with little vegetation, and stony or gravelly steppes; in *Caragana* thickets on stony steppe in Transbaikalia; generally in gravel or stony steppe, in meadow steppe and on dry slopes in Mongolia. In non-breeding season found in open country, from dry paddyfields, grassland and fallow fields to edges of cultivations; often in swampy areas on migration. To 3000 m in winter quarters; recorded to 6000 m on Mt Everest on migration.
Food and Feeding. Small insects and other invertebrates; also seeds. Forages on the ground, picking small items from surface; behaviour much as that of other grassland pipits.
Breeding. Laying in May. In display-flight, rises to 10-20 m, hovers while singing, then descends steeply to ground. Nest a well-camouflaged grass cup, on ground. Clutch 3-5 eggs; incubation by female, period 12-14 days; fledging period apparently not documented.
Movements. Long-distance migrant. Winters in Indian Subcontinent S to Sri Lanka, and also, uncommonly, in Myanmar; rare but regular in winter in SE Arabian Peninsula, where up to ten annually in United Arab Emirates. Recorded on passage through SE Tibet, Bhutan, Sikkim and Nepal during Aug to end Oct; arrival in winter quarters in early Sept, departure late Apr/May; arrives back on breeding grounds in Russia from early May. Vagrants recorded in many countries, e.g. in W to Israel and NW Europe (Norway, Sweden, Finland, Germany, Britain, France, Netherlands, Belgium), in E to Thailand and Japan; also Andaman Is, in NE Indian Ocean.
Status and Conservation. Not globally threatened. Widespread and common in breeding range; possibly extends farther S, into N China. Widespread and locally common winter visitor in India, although less common in S. Not considered to be at any risk.
Bibliography. 11. Tawny Pipit

Anthus campestris

French: Pipit rousseline **German**: Brachpieper **Spanish**: Bisbita Campestre

Taxonomy. *Alauda campestris* Linnaeus, 1758, Sweden.
Has sometimes been thought to form a superspecies with *A. similis*. In the past was sometimes treated as conspecific with *A. godlewskii*. Variation largely clinal, in N becoming smaller and paler from W to E, and in S becoming larger and greyer from NW Africa to Greece and then smaller and greyer E of there; naming of geographical races considered unwarranted by some taxonomists; alternatively, *kastschenkoi* included within nominate. Conversely, birds from N Iran and Turkey, intermediate in plumage between nominate and *griseus* but apparently larger than both, sometimes separated as race *boehmii*. Three subspecies recognized.
Subspecies and Distribution.
A. c. campestris (Linnaeus, 1758) - breeds from C & S Europe (Denmark and S Baltic S to Mediterranean countries) and NW Africa (Morocco E to Tunisia, possibly also SW Mauritania and NW Libya) E to SW Siberia and NW Kazakhstan and, in S, to N Iran and Turkmenistan; also locally in Middle East (Lebanon, S Syria, N Israel). Winters mainly in Africa and Arabia.
A. c. kastschenkoi H. C. Johansen, 1952 - S Siberia E to NW Mongolia; winters in S Asia.
A. c. griseus Nicoll, 1920 - SW Kazakhstan S to NE Iran and N Afghanistan, E to Dzhungarskiy Alatau Mts, extreme NW China (Tien Shan, in N Xinjiang) and SC Mongolia; winters in SW & S Asia.

Descriptive notes. 16·5-17 cm; 17-32 g, male average 29·5 g, female average 28 g. Fairly distictive pipit with rather uniform plumage, long tail and *Motacilla*-like stance. Nominate race has prominent creamy or buffish supercilium, blackish loral and moustachial stripes; lores and ear-coverts brown with creamy flecks; distinct, narrow dark brown malar streak; pale sandy brown above, sometimes with greyish tinge, indistinctly streaked blackish-brown, back and rump unmarked; flight-feathers and primary coverts dark brown with narrow white edges, tertials and greater wing-coverts paler with broad sandy-buff edges and tips, median coverts with blackish centres and broad buffish-white tips (indistinct wingbar), lesser coverts sandy brown; tail blackish-brown, central feather pair edged pale buff or buffy rufous, outer two pairs with pale buff wedges on inner web, white outer web and much of distal inner web; creamy white below, breast and flanks buff, breast with sparse short dark brown streaks; underwing-coverts and axillaries creamy buff; iris blackish-brown; bill dark brown, flesh-coloured base of lower mandible; legs bright yellowish flesh. Differs from *A. similis* in smaller size, more sandy and less grey plumage coloration. Sexes alike. Juvenile is scalloped or strongly streaked above, with tawny feather edges, median coverts edged and tipped whitish, forming more obvious wingbar, upper breast sharply streaked. Race *kastschenkoi* is smaller, paler and often more streaked than nominate; *griseus* is slightly larger than previous, also somewhat brighter grey (more brownish or sandy) above, with more contrasting ochre rump, more white below than previous, also on average smaller than nominate, with shorter wings and legs. VOICE. Song, in flight or from perch, a disyllabic or trisyllabic note, e.g. "tzirléé" or "tsirluéé or "tsirlííu", repeated at regular intervals of 1-3 seconds for up to a minute or more. Calls include explosive "chilp" or "chiip", a high-pitched sharp short "tschuwi" and, on take-off, a loud "tseep" or "tseuc", reminiscent of call of *Motacilla flava*; shrill "sree" and high-pitched "tji-tji-tji" near nest.
Habitat. Open dry habitats, from sand dunes, sandy heaths, dry grassland and clear-felled areas to artificial habitats such as gravel pits; steppe and semi-deserts in C & E parts of range. Favours areas with dwarf shrubs and low-growing trees for songposts. Lowlands to c. 450 m in Europe; to 2600 m in NW Africa and Caucasus; to 3600 m in E Kazakhstan.
Food and Feeding. Mainly insects, also other invertebreates, and seeds; rarely, small vertebrates (reptiles). Recorded prey include grasshoppers and locusts (Orthoptera), termites (Isoptera), dragonflies and damselflies (Odonata), mantids (Mantodea), adult and larval butterflies and moths (Lepidoptera), lacewings (Neuroptera), flies (Diptera), sawflies and ants (Hymenoptera), beetles (Coleoptera) and bugs (Hemiptera), as well as spiders (Araneae), harvestmen (Opiliones), slugs and snails (Mollusca). One record of sand lizard (*Lacerta agilis*) taken. In 41 items found in 12 stomachs from Moldova, 44% were beetles (mainly curculionids, carabids and chrysomelids), 19% orthopterans, 19% hymenopterans, 5% lepidopteran larvae, and seeds; in Crimea, 78·6% of items were curculionid and carabid beetles. Of 280 items fed to chicks in N Kazakhstan, 43% were orthopterans, c. 17·6% lepidopterans, c. 11% spiders, with dipterans, hemipterans and hymenopterans each forming 5-10%, and beetles, snails, lacewings and dragonflies each less than 5%. In African non-breeding quarters, locusts and grasshoppers, termites, assassin bugs (Reduviidae), caterpillars, hymenopterans, beetles and grass seed eaten. Forages mainly on the ground, by running and pecking. Occasionally jumps up to take flying insects, such as termites; only rarely flies after prey, or hovers to find it. Will stand on large items such as a grasshoppers, and dismember these by hammering with the bill.

Breeding. Season mid-Apr to mid-Aug, earlier in N Africa and later in N Europe (mid-Jun in Sweden); in W Europe two laying peaks (mid-May to early Jun, mid-Jun to early Jul) suggestive of double brooding. Monogamous; territorial. In display-flight, rises to c. 30 m, occasionally higher (to 150 m), sings while circling randomly on deeply undulating course; descent steep, or gliding and angled, sometimes with continued song. Nest built mainly by female, sometimes helped by male, a cup of grass stems, leaves and roots, lined with finer plant material and hair, built in scrape or hollow on ground or in tuft of grass. Clutch 3-6 eggs, mainly 4-5, mean 4·23 in S Sweden, 4·47 in Netherlands, 3·85 in E Germany; incubation by female, perhaps sometimes by both sexes, period 11·5-14 days, mostly 12 days; nestlings fed by both parents, for 13-14 days, post-fledging care also by both parents, for 4-5 weeks.

Movements. Almost wholly migratory. W populations winter predominantly in Sahel zone in sub-Saharan Africa, also in Nile Valley and region from S Sudan S to N Somalia and, more rarely, to Uganda and N Kenya; occasionally recorded farther S, e.g. Liberia E to Ghana; a few occasionally remain farther N, in E Mediterranean region, and small numbers spend non-breeding season in Sahara Desert (S Algeria). E populations migrate mainly to Arabian Peninsula and S Asia E to NW Indian Subcontinent, more rarely S to C peninsular India. Race *griseus* recorded on passage in Middle East and Egypt. Vagrants recorded N to Finland, Norway and British Is, also W to Madeira and Cape Verde Is.

Status and Conservation. Not globally threatened. Fairly common in much of range. Populations in W & C Europe have declined markedly following habitat loss from afforestation of open habitats, scrub encroachment and intensification of agriculture; climate change may also be implicated; in C Europe only isolated breeding sites remain, mainly at inland sand dunes, open-cast mines and forest clearings. Main European population lies in the maquis and garrigue of Mediterranean region and the steppe and semi-deserts of SE European Russia and Ukraine. In Africa, recently reported as breeding in Afrotropics, two nests being built in mid-May in N Somalia, and displaying individuals found on Ethiopian side of border in Apr-May 1995; further fieldwork required in order to ascertain whether breeding regular in this region; breeding also suspected in SW Mauritania and NW Libya, but no confirmation.

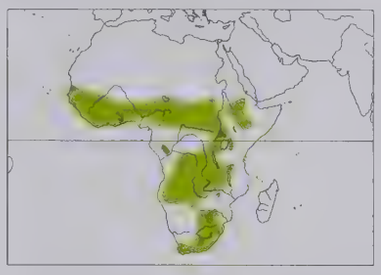
PLATE 72

inches 3

cm 8



12. Plain-backed Pipit

Anthus leucophrys

French: Pipit à dos uni **German**: Braunrückenpieper **Spanish**: Bisbita Liso

Taxonomy. *Anthus leucophrys* Vieillot, 1818, Cape of Good Hope, South Africa.
Races *goodsoni* and *saphiroi* of *A. vaalensis* included in present species by some authors. Variation partly clinal, with races intergrading from W to E; *ansorgei* also intergrades with *zenkeri* in Guinea-Bissau. Other described races are *prunus* (Angola), merged with *bohndorffi*, *turneri* (NW Kenya), synonymized with *zenkeri*, and *enunciator* (Swaziland), merged with nominate. Seven subspecies recognized.

Subspecies and Distribution.
A. l. ansorgei C. M. N. White, 1948 - S Mauritania, Senegal, Gambia and Guinea-Bissau.
A. l. zenkeri Neumann, 1906 - Guinea and S Mali E to Ghana, thence E to S Chad, Central African Republic and S Sudan, and S to Cameroon, N & E DRCongo, Burundi, NW Tanzania and W Kenya.
A. l. gouldii Fraser, 1843 - Sierra Leone, Liberia and Ivory Coast.
A. l. omoensis Neumann, 1906 - SE Sudan and N, C & W Ethiopia.
A. l. bohndorffi Neumann, 1906 - SE Gabon, C PRCongo, and S DRCongo E to W Tanzania and S to C Angola, NW Zambia and N Malawi (R Songwe).
A. l. tephridorsus Clancey, 1967 - S Angola and S Zambia S to N Namibia, NW Botswana and NE Zimbabwe.
A. l. leucophrys Vieillot, 1818 - SE Botswana E to extreme S Mozambique, S to E & S South Africa.

Descriptive notes. 15-17 cm; 21-32 g. Nominate race has buffy supercilium, brown lores and ear-coverts, latter mottled buffish, dark eyestripe and moustachial stripe, faint dark malar stripe; upperparts olive-brown above, faintly streaked on head; remiges and larger wing-coverts blackish-brown, secondaries with broad sandy-brown edgings, tertials and greater and median wing-coverts with broad sandy-brown edges and tips, lesser coverts brown; tail blackish-brown, T5 with pale brown outer web and tip of inner web, T6 wholly pale brown; pale buff below, paler on chin and throat, browner on breast, upper breast with indistinct brown streaking; underwing-coverts and axillaries warm buff; iris dark brown; bill blackish-brown, base of lower mandible yellowish flesh; legs pale brown or flesh-brown to pinkish-buff, hind claw at least 12 mm. Distinguished with difficulty from very similar *A. vaalensis* by slightly darker coloration above and below, base of lower mandible usually yellowish (variable); in the hand, also has stouter, straighter, on average slightly longer hind claw. Sexes alike. Juvenile is browner, with upperparts, wing-coverts and tertials narrowly edged buffish, obvious short dark brown streaks on breast. Race *tephridorsus* is paler and more greyish above than nominate; *bohndorffi* is browner and less olive above, and paler below; *zenkeri* is browner above than previous, with more cinnamon edges of wing feathers, and deeper cinnamon-tinged buff below, rectrix T5 with only the tip pale, hind claw shorter; *omoensis* is larger and darker than last, supercilium extending well behind eye, richer cinnamon below, heavier breast streaking; *gouldii* is smaller, rather dark above, with less cinnamon on wings, paler and more creamy below, more distinctly streaked on breast; *ansorgei* is greyer and paler above, belly creamy, breast with distinct broad dark streaks. Voice. Song, from ground or perch, an unstructured monotonous series of well-spaced phrases, "chwee-chweep-chwee" or "tjeeh tjup three tweeh tjeeh", like those of a sparrow (*Passer*); sometimes includes a more distinctive short low-pitched trill. Alarm call a thin, soft "chissik"; sparrow-like "t-t-tit" when flushed.

Habitat. Savanna with scattered trees and bushes in better-wooded areas, open grassland with scattered bushes. Occurs in various open habitats, from short or burnt grassland to fallow land and arable fields. Where sympatric with *A. vaalensis*, as in Botswana and Zimbabwe, favours floodplains and other wet grasslands. Generally low to medium elevations, but to 2200 m in E Africa.

Food and Feeding. Insects and their larvae, especially caterpillars (Lepidoptera) and grasshoppers (Orthoptera); also seeds. In stomach contents from S Africa, beetles (Coleoptera), particularly weevils (Curculionidae), and mantids (Mantodea) and insect larvae (mainly of coleopterans and lepidopterans) the main components of diet; soldier termites (Isoptera), grasshoppers and ants (Hymenoptera), and some seeds, were also found in stomachs. Forages on the ground; probably takes more food from vegetation than from ground surface.

Breeding. Breeds mainly during rains: Apr-Jun in Senegambia, Jan-May in Sierra Leone, Feb-Jun in Ghana, juvenile in Jul in Burkina Faso; in all months in S Nigeria but mainly Mar-May in N; Mar-Jun and Aug in Kenya, Aug in SW Tanzania, Sept-Nov in Zambia; in South Africa Sept-Dec in N, Oct-Dec in E & S. Monogamous; territorial, but sometimes several pairs nest close together. Nest a deep grassy cup, lined with finer rootlets, hair or even feathers and fur, built on ground close to a grass tussock. Clutch 2-3 eggs, occasionally 4; incubation and fledging periods not documented; young fed by both parents.

Movements. Little known; some populations believed to be sedentary, with others making altitudinal or nomadic movements.

Status and Conservation. Not globally threatened. Uncommon to locally common. Fairly catholic in its choice of habitats, and unlikely to be at any risk in the long term. Clearing of land for agriculture may have been beneficial to this species.

Bibliography. Anon. (1986), Archer & Godman (1937-1961), Ash & Miskell (1998), Atkins (1988), Bannerman (1953), Barlow *et al.* (1997), Benson & Benson (1977), Benson *et al.* (1971), Borrow & Demey (2001), Campbell (1989, 1990), Chapin (1953), Cheke & Walsh (1996), Clancey (1958b, 1964b, 1967a, 1990a), Dean (1974, 2000), Dowsett & Dowsett-Lemaire (1993, 1997), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), van den Elzen (1975), Gatter (1997), Ginn *et al.* (1989), Gore (1990), Grimes (1987), Hall (1959), Harrison *et al.* (1997), Hockey *et al.* (1989), Hustler (1997), Jackson & Elgar (1993), Jellicoe (1954), Keith *et al.* (1992), Kopij *et al.* (2002), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993a), Martin (1992), McAllister (1990), McCleland (1987), Mendelsohn (1984a, 1984b), Morel & Morel (1990), Nikolaus (1987), Pedersen (2000), Penry (1994), Rodwell *et al.* (1996), Salewski (2000), Short *et al.* (1990), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Stevenson & Fanshawe (2002), Stjernstedt (2004), Tarboton (2001), Voelker (1999c), White (1948).

13. Long-tailed Pipit

Anthus longicaudatus

French: Pipit à longue queue **German**: Langschwanzpieper **Spanish**: Bisbita Colilargo

Taxonomy. *Anthus longicaudatus* Liversidge, 1996, Kimberley, South Africa.
Monotypic.

Distribution. Little known. Occurs in austral winter in C South Africa: observed in Kimberley area (E Northern Cape-W Free State), and recorded also from near Colesberg (S of R Orange) and Beaufort West (E Western Cape). Probably breeds farther N, on Barotse floodplains in Zimbabwe.

Descriptive notes. 15-16 cm; 30·2-34 g. Medium-sized to large, plain-backed pipit. Has broad off-white supercilium and submoustachial stripe, dark eyestripe, narrow dark moustachial and malar stripes; ear-coverts grey-brown, bordered black at rear; above, plain darkish grey-brown with pale feather edgings; wing feathers dark brown with pale edgings; tail dark brown, outer feather with tip and outer web buff to creamy; upper throat whitish, lower throat to upper belly white with indistinct brownish spots, lower belly, flanks and undertail-coverts brownish to brownish-white; iris dark brown; bill darkish horn, lower mandible paler with dark tip; legs horn-brown. Distinguished from similar *A. vaalensis* and *A. leucophrys* by darker back, longer darker tail, shorter bill, longer tarsus, shorter hind claw; in the hand, primary P9 equal to P6, rather than P7 or P8. Voice. Single note uttered when flying away; unlike e.g. *A. leucophrys*, call not polysyllabic.

Habitat. Breeding habitat unknown. In non-breeding area occurs on short dry grassland, including urban parks and playing fields.

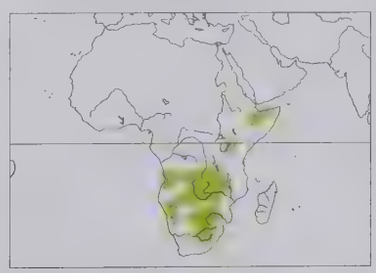
Food and Feeding. Diet not known. Forages on ground in grass, as other pipits. In non-breeding area occurs in flocks of 10-40 individuals, often with *A. vaalensis*, *A. cinnamomeus* and *A. similis*; differs from them in horizontal, rather than upright, posture, and exaggerated tail-wagging behaviour.

Breeding. Unknown.

Movements. Uncertain. Believed to migrate from presumed breeding grounds in Zimbabwe (Barotse floodplain) S to South Africa; non-breeding area probably from NE Northern Cape and W Free State S to R Orange. Passage S through Kimberley occurred in early May 1999, but recorded at Kimberley as early as Feb.

Status and Conservation. Not globally threatened. Data-deficient. Very poorly known species, only recently described. Unknown away from the Kimberley playing fields and surrounding farms. Fieldwork required in this region and in neighbouring areas, including countries bordering South Africa, in order to determine the species' breeding range and the extent of its non-breeding range.

Bibliography. Anon. (1997e, 1997f, 1997g), Atkinson (1997), Harrison *et al.* (1997), Hockey (1997b), King (1997), Liversidge (1996, 1998), Louette & Prévost (1987), Martin (1992), Sinclair & Ryan (2003), Stattersfield & Capper (2000), Tarboton (2001), Voelker (1999a, 1999b, 1999c), Voelker & Edwards (1998).



14. Buffy Pipit

Anthus vaalensis

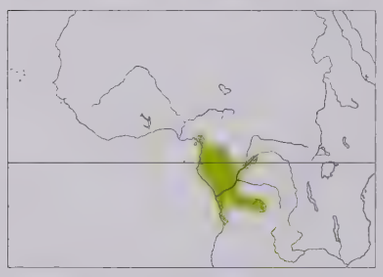
French: Pipit du Vaal **German**: Vaalpieper **Spanish**: Bisbita del Vaal
Other common names: Sandy (Plain-backed) Pipit

Taxonomy. *Anthus vaalensis* Shelley, 1900, Newcastle, KwaZulu-Natal, South Africa.
Was in the past confused with *A. leucophrys*; NE races *saphiroi* and *goodsoni* still included in that species by some authors. Race *chobiensis* possibly better merged with *neumanni*, and *marungensis* possibly indistinguishable from either of those two. Proposed race *daviesi* (Eastern Cape, South Africa) included in nominate, and *muhingae* (SE DRCongo) in *neumanni*; birds of SE Botswana and NE South Africa sometimes separated as race *clanceyi*. Geographical limits of races difficult to establish; boundaries between listed ranges tentative. Eight subspecies provisionally recognized.

Subspecies and Distribution.
A. v. saphiroi Neumann, 1906 - SE Ethiopia and NW Somalia.
A. v. goodsoni Meinertzhagen, 1920 - C & SW Kenya and extreme N Tanzania.
A. v. neumanni Meinertzhagen, 1920 - Angolan plateau and SC & S DRCongo; moves S to Namibia and Botswana in the rains.
A. v. chobiensis (Roberts, 1932) - SE DRCongo and W Tanzania S to SE Angola, extreme NE Namibia, N Botswana, Zimbabwe and adjacent Mozambique.
A. v. marungensis Chapin, 1937 - N Zambia E to S Tanzania.
A. v. namibicus Clancey, 1990 - NE & C Namibia.
A. v. exasperatus Winterbottom, 1963 - NE Botswana; migrates to W Zimbabwe.
A. v. vaalensis Shelley, 1900 - S Botswana E to S Mozambique, NE South Africa and W Lesotho.

Descriptive notes. 15-18·5 cm; 23-36·6 g. Large pipit with plain upperparts. Nominate race has broad buff supercilium, dusky lores, sandy-brown ear-coverts, dark brown moustachial stripe and narrow malar stripe; sandy brown above, faint dark streaking on head; remiges and wing-coverts brown, tertials and greater and median wing-coverts with broad buff edges and tips, lesser coverts sandy brown; tail dark brown, T5 with buff tip and outer edge, T6 with pale buff outer web and distal part of inner web; pale sandy buff below, paler on chin and throat, darker on breast, upper breast indistinctly streaked greyish-brown; underwing-coverts and axillaries pale buff; iris dark brown; bill dark brown, pinkish base of lower mandible; legs pale yellowish-brown, hind claw relatively short (less than 11 m). Distinguished

On following pages: 15. Long-legged Pipit (*Anthus pallidiventris*); 16. Nilgiri Pipit (*Anthus nilghiriensis*); 17. Upland Pipit (*Anthus sylvanus*); 18. Berthelot's Pipit (*Anthus berthelotii*); 19. Malindi Pipit (*Anthus melindae*); 20. Striped Pipit (*Anthus lineiventris*); 21. Yellow-tufted Pipit (*Anthus crenatus*).



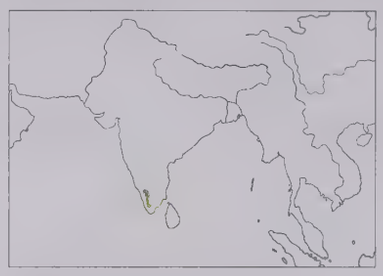
with difficulty from *A. leucophrys* by somewhat paler plumage, pinkish (not yellowish) on lower mandible, shorter and more curved hind claw. Sexes alike. Juvenile is browner above than adult, feathers edged pale buff, distinct dark spotting on breast. Race *saphiroi* is more warm brown above, extensively sandy buff below, more distinct streaks on breast; *goodsoni* is generally paler and browner above, sandier wing edgings than nominate, paler below; *marungensis* is larger, greyer above and more rufous-buff below than previous, has faint dusky spots on breast; *neumanni* is smaller, less deeply coloured than previous, slightly darker and browner above and deeper buff below than nominate; *chobiensis* is smaller than nominate, less sandy and more vinaceous above, with wing-coverts and underparts more cinnamon-buff; *namibicus* is dark, more blackish above, underparts paler and more vinous-buff; *exasperatus* is smaller than nominate, with upperparts colder and greyer. Voice. Song a series of very high rapid "trowhee" with well-spaced phrases; also described as rather dry and monotonous notes, "chrep, chiri, chree, chreu", regularly spaced at c. 1-second intervals; very similar to song of *A. nyassae*. Call "chik", "chipip" or "chipipip".
Habitat. Open grassland and overgrazed areas with bare ground, fallow land, recently burnt areas and edges of pans; may also use clearings in open woodland. Occurs in generally drier habitats than *A. leucophrys* in those areas where the two overlap in range. Ranges from lowlands up to at least 1700 m.
Food and Feeding. Insects and other invertebrates; also seeds. Beetles (Coleoptera), grasshoppers (Orthoptera), ants (Hymenoptera), termites (Isoptera) and caterpillars (Lepidoptera) are important prey. Of 67 stomachs examined in Zimbabwe, 76% contained coleopterans, 69% orthopterans, 34% hymenopterans, 18% bugs (Hemiptera), 19% lepidopterans, 24% termites, 3% flies (Diptera), 4% dragonflies and damselflies (Odonata), 6% myriapods, 3% Dictyoptera, 6% arachnids, 7% seeds; feathers and grit found in, respectively, 6% and 5% of stomachs. Forages on the ground while walking.
Breeding. Lays before or during rains in S Africa, Jun-Oct in Zambia, Jul-Feb (mainly Sept-Dec) in Zimbabwe, Aug-Dec in South Africa. Monogamous; territorial. Nest a large, loosely built cup of coarse grass, with lining of finer grasses and rootlets, hidden in depression at base of grass tussock or rock. Clutch 2-3 eggs; incubation and fledging periods unknown.
Movements. Little known; some populations thought to be sedentary, and others to make regular movements. Some S populations believed to be nomadic, especially during austral winter. Races *chobiensis* and *neumanni* possibly migrate to S Africa after breeding.
Status and Conservation. Not globally threatened. Status not well known; apparently uncommon to locally common. May have benefited from the clearance of land for agriculture and stock grazing. No obvious threats.
Bibliography. Archer & Godman (1937-1961), Atkins & Johnston-Stewart (1989), Benson & Benson (1977), Benson *et al.* (1971), Borrett (1969b), Borrett & Wilson (1971a), Campbell (1989, 1990), Chapin (1953), Clancey (1960a, 1964b, 1968a, 1990a), Dean (1978, 2000), Frost & Siegfried (1975), Ginn *et al.* (1989), Hall (1959), Harrison *et al.* (1997), Keith *et al.* (1992), Liversidge (1998), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993a), Newman *et al.* (1992), Pedersen (2000), Penry (1994), Short *et al.* (1990), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Stevenson & Fanshawe (2002), Stjernstedt (2004), de Swardt (1990a), Tarboton (2001), Voelker (1999c), White (1948), Winterbottom (1963).

15. Long-legged Pipit

Anthus pallidiventris

French: Pipit à longues pattes **German**: Stelzenpieper **Spanish**: Bisbita Patilargo

Taxonomy. *Anthus pallidiventris* Sharpe, 1885, Gabon.
Race *esobe* intergrades with nominate in region of Bolobo, on middle R Congo. Two subspecies recognized.
Subspecies and Distribution.
A. p. pallidiventris Sharpe, 1885 - SW & S Cameroon S to N Angola (S to W Cuanza Sul and Lunda Sul).
A. p. esobe Chapin, 1937 - middle Congo Basin.



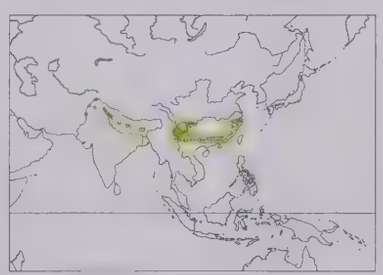
Descriptive notes. 18 cm. Large, plain-backed pipit with long legs and bill, long hind claw, and upright stance. Nominate race has prominent whitish supercilium, brown lores and ear-coverts with pale buff flecks, and dark brown moustachial stripe; overall greyish-brown above, slightly streaked on head; remiges dark brown, tertials and greater and median wing-coverts are dark brown with buff tips and edges, lesser coverts brown; tail blackish-brown, with T5 buffish-brown with pale edges and tip, and T6 buffish-brown; whitish below, breast washed with greyish-buff and with indistinct brown streaking, flanks pale buff; underwing-coverts and axillaries brownish-white; iris blackish; bill brown, with conspicuous yellow base of lower mandible; legs pale brown. Sexes alike. Juvenile is more streaked on crown than adult, supercilium buff, feathers of upperparts and wings tipped and fringed tawny, breast mottled black. Race *esobe* differs from nominate in having darker and more grey-brown upperparts, more pronounced breast streaking. Voice. Song a repeated "tit-tidii". Contact call "psip"; flight call liquid "poui-titit"; husky "ptic-ptic".
Habitat. Patches of natural grassland, including forest clearings, as well as pastures, grassland and bare ground in and around villages and towns, and cultivated land; also airfields.
Food and Feeding. Food arthropods, such as small grasshoppers (Orthoptera), other small flying insects, and spiders (Araneae). Forages on the ground, running to pick insects from ground surface and low vegetation; jumps up to catch flying insects. Walks and runs with upright stance, constantly wagging tail up and down.
Breeding. Little information. Laying in May and Jul-Aug in Gabon; eggs in Aug in PRCongo; nestling in Jan in DRCongo, but possibly breeds also May-Jul, at end of rains; gonadal condition of specimens indicates breeding probably in Sept-Oct in N Angola (Cabinda). No other information.
Movements. Apparently resident over much of range, but thought to be locally nomadic in non-breeding season.
Status and Conservation. Not globally threatened. Locally common; more widely distributed than was previously thought. Has recently extended its range NW from Gabon to SW Cameroon, and two possible sightings in SE Nigeria; expansion possibly a result of deforestation. Will forage close to human habitations and on other man-altered habitats; unlikely to be at any risk in foreseeable future.
Bibliography. Bannerman (1953), Borrow & Demey (2001), Brosset & Érard (1986), Christy & Clarke (1994), Clancey (1990a), Dean (2000), Dean *et al.* (2003), Demey (2003), Demey *et al.* (2000), Dowsett (1989), Dowsett & Dowsett-Lemaire (1991), Fishpool & Evans (2001), Keith *et al.* (1992), Lippens & Wille (1976), Mackworth-Praed & Grant (1963, 1973), Pedersen (2000), Traylor (1963), White (1951).

16. Nilgiri Pipit

Anthus nilghiriensis

French: Pipit des Nilgiri **German**: Nilghiripieper **Spanish**: Bisbita de los Nilgiri

Taxonomy. *Anthus nilghiriensis* Sharpe, 1885, Nilgiri Hills, southern India.
Initially named as *A. rufescens*, but that name invalid. Monotypic.
Distribution. Western Ghats in Kerala and W Tamil Nadu, in extreme SW India.



Descriptive notes. 17-17·5 cm. Richly coloured pipit with heavy streaking. Has broad deep buff to whitish supercilium, darker buff ear-coverts, sometimes some dark spots in malar region; crown and upperparts tawny-olive or warm grey-brown with greenish-yellow tinge, crown to mantle and scapulars heavily streaked blackish-brown, back to uppertail-coverts streaked grey-brown; remiges and wing-coverts dark brown, edges and tips dull dark buff to greenish-yellow (forming two wingbars); tail dark brown, outer two feather pairs with prominent whitish wedges; throat, breast and flanks deep buff, belly paler buff, blackish-brown streaks on breast and flanks; iris dark brown; bill blackish, lower mandible with greyish-pink base; legs pale pink or yellowish-pink. Distinguished from *A. rufulus* by shorter tail, more boldly streaked crown and mantle, more distinct buffish supercilium, richer buff underparts with bolder markings, no malar stripe. Sexes alike. Juvenile is generally paler than adult, with more distinct streaking. Voice. Song, usually from ground, feeble, initially quiet and hesitant, accelerating into trill, "tsip tsip tsip-tsip-sip-sip-sipsipsipsipsip" and ending abruptly. Call a weak "see see", unlike that of *A. rufulus*.
Habitat. Upland grassland, open grassy and rocky areas on tops of hills; favours short grass. Also in coffee plantations. Occurs at 1500-2300 m; down to 1000 m in Panmudi Hills. In Nilgiri Hills, replaces *A. rufulus* above 1800 m (although some overlap).
Food and Feeding. Small invertebrates. Forages on ground, in short grass; when disturbed, flies to nearest bush or tree.
Breeding. Season end Mar/early Apr to Jul. Nest a shallow cup of coarse grass and roots, lined with finer grass, sometimes hair and stems, built among roots or in tuft of grass or in depression at base of bush on open hillside or bank. Clutch 2-4 eggs; no further information.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Western Ghats EBA. Locally fairly common to common in Nilgiri Hills, Palni Hills and High Range, and in Panmudi Hills. Total range, however, is small, and its grassland habitats are gradually being converted to plantations of tea, gum (*Eucalyptus*) and wattle (*Acacia dealbata*). Further deterioration and loss of habitat could place this species at risk.
Bibliography. Ali (1969), Ali & Ripley (1998), Alström & Mild (2003), Baker & Inglis (1930), Beadnell (1936), Collar *et al.* (2001), Daniels (1997), Grimmett *et al.* (1998), Kazmierczak (2000), Martens & Eck (1995), Ripley (1982), Stattersfield & Capper (2000), Zacharias & Gaston (1999).

17. Upland Pipit

Anthus sylvanus

French: Pipit montagnard **German**: Mattenpieper **Spanish**: Bisbita del Himalaya
Other common names: Indian/Oriental/Chinese Pipit

Taxonomy. *Heterura sylvana* Hodgson, 1845, central Nepal.
Slightly paler and less streaked birds from W part of range (Punjab region) described as race *oreinus*, but variation considered part of a cline. Monotypic.
Distribution. From NW & N Pakistan (possibly from E Afghanistan) E in Himalayas at least to E Nepal, and in S & SE China (W & S Sichuan and from Yunnan E to Zhejiang and Fujian, also Hong Kong); possibly also N & NE Myanmar.

Descriptive notes. 17 cm; 18·7 g. Large, streaked pipit with stout, relatively short bill. Has creamy supercilium, indistinct dark moustachial stripe and malar stripe; grey-brown above, mantle and scapulars more buffy, boldly streaked blackish-brown; wing feathers with narrow sandy edges; tail dark grey-brown, outer three feather pairs with pale wedge on inner webs, outer two pairs with mostly whitish outer webs; upper throat and belly buffish-white, rest of underparts pale buff, prominent blackish-brown streaks on breast and flanks, fine streaks on undertail-coverts; iris dark brown; upper mandible blackish, lower mandible pale pinkish with dark tip; legs pale pinkish. Differs from *A. richardi* in having more boldly streaked upperparts, more extensive and narrower streaks on breast and belly, stouter bill. Sexes alike. Juvenile has prominent pale buffish feather tips and edges above, giving scaly appearance, whiter underparts with streaks paler. Voice. Song, from prominent feature (e.g. rock, bush, tree) or in flight, a repeated "seetyu-seetyu" with stress on first syllable or "tyu-see, tyu-ee" with stress on second syllable, not unlike a Great Tit (*Parus major*) song; also described as rather pleasant but monotonous "weeeee tch weeeee tch" or drawn-out whistling "wichee wichee wichee", likened to that of some buntings (*Emberiza*); unlike songs of other members of genus. Call, infrequently given, a "chirp" like that of a sparrow (*Passer*), unlike high-pitched notes of other pipits.
Habitat. In breeding season occurs on steep rocky and grassy slopes with scattered bushes or rocks, also on abandoned terrace cultivation; often associated with chir pine (*Pinus roxburghi*) or scattered blue pine (*P. wallichiana*) in drier foothills of Pakistan, and found in open *Pinus longifolia* forest in India. Breeds mostly at 1200-3000 m, but to 2300 m in Pakistan, and locally down to 900

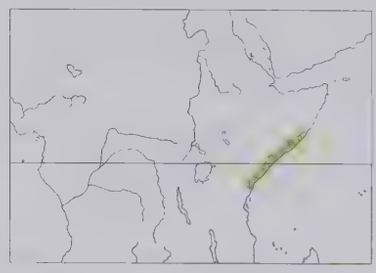
m in N India (Himachal Pradesh), and locally down to 500 m in S China (Hong Kong). In similar habitats in winter, but generally at lower elevations (down to c. 900 m).
Food and Feeding. Little known. Small invertebrates. Feeds on the ground, creeping in horizontal posture. When disturbed, often adopts upright stance and makes tail-flicking movements.
Breeding. Breeds Mar-Jul. Occasional brief song flight, rising a short distance and then parachuting downwards on partly spread wings. Nest a cup of coarse grass, lined with finer grass, well hidden under tuft of grass or rock. Clutch 3-5 eggs; incubation and fledging periods not documented. Nests occasionally parasitized by Common Cuckoo (*Cuculus canorus*).
Movements. Resident; some altitudinal movements. In winter, descends from highest areas of Himalayas, down to 900 m, and in Nepal occurs at 1350-2000 m in non-breeding season. Apparently resident in mountains of China.
Status and Conservation. Not globally threatened. Widespread and locally fairly common in India, Nepal and China. Scarce to rare and localized in Pakistan, where occurs in only a few areas in N & W (S to Sulaiman Range, in Baluchistan). Not well known.
Bibliography. Ali (1979), Ali & Ripley (1998), Alström & Mild (2003), Carey *et al.* (2001), Cerny (1988), Cheng Tsohsin (1987), Dhinsa & Sandhu (1988), Étchécopar & Hüe (1983b), Grimmett *et al.* (1998, 2000), Hüe & Étchécopar (1970), Kazmierczak (2000), King *et al.* (1975), La Touche (1931-1934), Lekagul & Round (1991), MacKinnon & Phillipps (2000), Martens & Eck (1995), Ripley (1982), Roberts (1992), Shrestha (2000), Smythies (1986).

18. Berthelot's Pipit

Anthus berthelotii

French: Pipit de Berthelot **German**: Kanarenpieper **Spanish**: Bisbita Caminero
Other common names: Canarian/Canary Islands Pipit

Taxonomy. *Anthus Berthelotii* Bolle, 1862, Canary Islands.
Relationships uncertain; believed to be closest to *A. campestris*, but behavioural aspects suggest possible affinities with *A. similis*. Race *madeirensis* sometimes subsumed in nominate. Birds from Lanzarote, described as race *lanzaroteae*, considered indistinguishable from nominate. Two subspecies recognized.
Subspecies and Distribution.
A. b. madeirensis Hartert, 1905 - Madeira Archipelago (Madeira, Desertas and Porto Santo, reported also from Baixo I).
A. b. berthelotii Bolle, 1862 - Selvagens and Canary Is.



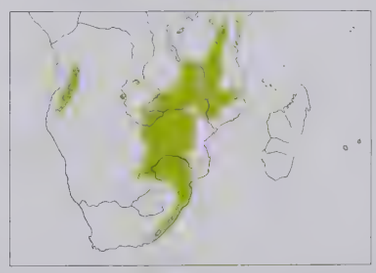
Descriptive notes. 14 cm; 16-19 g. Has long white supercilium, unstreaked pale lores and cheeks, dark brownish-grey moustachial and malar stripes; crown and upperparts ashy brown, black streaks on head, dark brown streaks on mantle and back, plain lower back and rump, uppertail-coverts warmer brown with slight streaking; primaries, secondaries and primary coverts dark brown with narrow white edges, tertials and greater wing-coverts paler with broad sandy-buff edges and tips, median coverts blackish-centred with broad buff-white tips (forming wingbar), lesser coverts sandy brown; tail blackish-brown, T5 with outer web and much of distal inner web white, T6 white; whitish below, breast tinged pink or buff and streaked dark grey-brown, flanks and undertail-coverts usually thinly streaked dark; colour of underparts varies according to soil type (plumage becomes earth-stained); iris dark brown; upper mandible grey, lower mandible pale pink; legs pale pink or yellowish-pink. Sexes alike. Juvenile has broader and clearer streaks above, pale feathers edgings giving scalloped appearance, back, rump and uppertail-coverts more rufous, greater contrast on wings, more spotted than streaked below. Race *madeirensis* has longer and stouter bill than nominate. Voice. Song, from elevated perch or in flight, pleasant and cheerful series of "tschrli", "truit", "tsliu" or "tsiree", notes separated by pauses of 1-2 seconds. Main calls "zichéé" or "sliréé" when flushed, also low hoarse "tiuee", "chiriree", "tschir", "tchik", "sleeoo" and similar; "tsrl" contact call at nest. All vocalizations similar to those of *A. campestris*.
Habitat. Occurs in all habitats except thick woodland and moister parts, from sea-level to over 2000 m. In E Canaries, prefers dry, sparsely vegetated semi-desert areas of volcanic rock and other open places, such as tracks; occurs on rock-strewn hillsides on more mountainous W islands. In Madeira, most frequent in high serras but occurs also on cliffs and in fields near sea.
Food and Feeding. Food mainly insects, such as grasshoppers and crickets (Orthoptera) and caterpillars (Lepidoptera), also other arthropods, and seeds. Stomachs contained small ants (Hymenoptera), spiders (Araneae), flies (Diptera), lepidopteran pupae, and weed seeds; others were full of large plant seeds. Forages on the ground, pecking among grass or stones, or rushing forward to pick active prey, or occasionally making brief aerial sally. Has habit of running along ground, rarely flying far, and standing upright.
Breeding. Late Jan-Aug, starting later at higher altitudes; probably double-brooded. In song flight, rises to 30 m or more, flies with deep undulations in irregular circles, drops steeply or in angled glide. Nest a cup of dry grass and roots, occasional feather incorporated, lined with hair, wool and/or feathers, built in shelter of small bush or stone. Clutch 2-5 eggs, mainly 3-4; incubation and fledging periods not documented.
Movements. Resident; no evidence of seasonal altitudinal movements.
Status and Conservation. Not globally threatened. Restricted-range species: present in Madeira and the Canary Islands EBA. Common in suitable habitat, where one of the most numerous bird species in its range. Canaries population comprises 15,000-20,000 individuals; Madeiran race estimated at c. 500-1000 breeding pairs. Population considered stable. No known threats at present, but any future large-scale developments may impinge on its habitats.
Bibliography. Alström & Mild (1993, 2003), Arctander *et al.* (1996), Bannerman (1963), Bannerman & Bannerman (1965), Bourne (1995), Clarke & Collins (1996), Collins (1984), Concepción (1992), Cramp (1988), Dunn (1994), Ennion & Ennion (1962), Étchécopar & Hüe (1964), Folmer & Ortvad (1992), Hagemeijer & Blair (1997), Hammer (1993), Heath & Evans (2000), Heath *et al.* (2000), Hildén & Hildén (1995), Juergens (2002), Lorenzo & Barone (2003), Martín & Lorenzo (2001), Snow & Perrins (1998).

19. Malindi Pipit

Anthus melindae

French: Pipit de Melinda **German**: Malindipieper **Spanish**: Bisbita de Malindi

Taxonomy. *Anthus melindae* Shelley, 1900, Malindi, Kenya.
Possibly related to *A. cinnamomeus* and *A. pseudosimilis*. Two subspecies recognized.
Subspecies and Distribution.
A. m. mallablensis Colston, 1987 - coast of S Somalia from 30 km NE of Mogadishu S to c. 1° N.
A. m. melindae Shelley, 1900 - S Somalia (S from lower R Juba and lower R Shabelle and, on coast, from Mogadishu) S to coastal Kenya (S to lower Tana Valley and Mombasa).



Descriptive notes. 14·5-16 cm; 19-27 g. Large, distinctive, long-legged pipit. Has whitish supercilium, brown lores, moustachial area and eyestripe, broad buff line below eye to ear-coverts, prominent dark brown malar stripe; earth-brown above, streaked dark brown on top of head, indistinctly mottled with dark brown on mantle; remiges and upperwing-coverts dark brown, tertials and greater coverts edged rich buff, median coverts and alula edged whitish (indistinct wingbar); tail blackish-brown, T5 tipped whitish, T6 pale brown with whitish tip and outer edge; whitish below, more greyish-buff on breast and flanks, brown streaking on breast, less so on flanks; underwing-coverts and axillaries greyish-brown; iris dark brown; bill dark horn, bright yellowish-flesh base of lower mandible; legs bright yellowish flesh-coloured. Sexes alike. Juvenile is darker and browner above, feathers of upperparts and wing-coverts narrowly edged whitish. Race *mallablensis* is smaller than nominate and has lighter brown head and upperparts. Voice. Song, from perch usually 1-1·5 m above ground, a jangling "creer", "kwee" or "kuree" repeated at 1-second intervals. Commonest call, in flight, a "tsweep" like that of *Motacilla flava*; also "tweet-tweet" and "tirrip-tirrip-tirrip".
Habitat. Low-lying coastal or riparian grassland, subject to seasonal flooding, which is well grazed or seasonally burnt. In Somalia, occurs in open lowland country, fixed dunes, cultivations and wetland edges.
Food and Feeding. Small invertebrates. Items taken from the ground or from the base of grass stems; locusts (Orthoptera) sometimes caught in the air. Observed to carry locusts to tracks and to thrash or dismember the insects on the firm surface. Usually seen singly, in pairs, or in small groups or loose flocks of up to 20 individuals.
Breeding. Laying during the rains, Apr-Jun, in Kenya; one record of two half-grown nestlings in early Jun in Somalia. Monogamous; territorial. Nest a deep thick-walled grass cup, attached to growing grass, in grass tussock; depth and thickness of nest possibly a strategy to protect eggs and young from temporary flooding. Clutch 2-3 eggs; incubation and fledging periods not documented.
Movements. Apparently resident; some local dispersive movements. May be an occasional wanderer in Kenya S of Ras Ngomeni.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Locally common to abundant in most of range; rare in Kenya S of R Sabaki. In Kenya, 4-5 birds/ha, or c. 2 pairs/ha, found in littoral grassland at Kampi ya Waya (N of R Sabaki) in May 1976; density may be higher, as 4 nests and a pair feeding flightless young found in area of less than 1 ha in May-Jun 1976, alongside *Tmetothylacus tenellus*, *Macronyx aurantiigula* and *A. cinnamomeus*. Any cessation of grazing or burning could render grassland habitats unsuitable, as this species avoids rank grassland. Moreover, growing demand for arable and grazing land is placing increasing pressure on diminishing wetlands in much of its small range; high levels of grazing pose additional threat.
Bibliography. Ash & Miskell (1998), Bennun & Njoroge (1999), Bliss (1997), Britton & Britton (1978), Brown & Britton (1980), Clancey (1990a), Collar *et al.* (1994), Colston (1982a, 1982b, 1987), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fanshawe & Bennun (1991), Fishpool & Evans (2001), Hall & Moreau (1970), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960), Muriuki *et al.* (1997), Pearson (1990), Short *et al.* (1990), Stattersfield & Capper (2000), Stevenson & Fanshawe (2002), Taylor (1983), Turner (1991), White (1961a), Zimmerman *et al.* (1996).

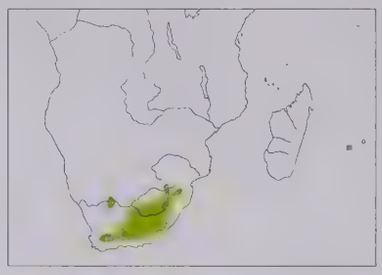
20. Striped Pipit

Anthus lineiventris

French: Pipit de Sundevall **German**: Streifenpieper **Spanish**: Bisbita Rayado
Other common names: Large Striped Pipit

Taxonomy. *Anthus lineiventris* Sundevall, 1850, Mohapoani, Limpopo River, Botswana.
Was previously sometimes thought to form a superspecies with *A. crenatus*, but the two species differ widely in plumage characters and ecology. Described race *sylvivagus* included in nominate and *angolensis* (from Angola) in *stygium*; furthermore, *stygium* considered by some authors to be indistinguishable from nominate. Two subspecies recognized.
Subspecies and Distribution.
A. l. stygium Clancey, 1952 - W Angola, and disjunctly from NW & W Tanzania, SE Kenya (Taita Hills, Chyulu Hills), SE DRCongo and W, E & S Zambia S to NE Botswana, Zimbabwe, N, W & S Mozambique and coastal E South Africa.
A. l. lineiventris Sundevall, 1850 - SE Botswana E to NE South Africa and W Swaziland.

Descriptive notes. 17-18 cm; male 30·3-35·3 g, female 31·8-37·3 g, unsexed 29·9-38 g. Large pipit with distinctive greenish edges of wing feathers, heavily streaked underparts. Nominate race has long, narrow buff supercilium, dark brown lores and ear-coverts with buff flecking, narrow dark malar stripe; above, pale olive-brown with dark brown streaking, streaks less distinct on back and rump; remiges, primary coverts and alula dark brown with yellowish-green edging, tertials and rest of upperwing-coverts tipped and edged olive-brown; tail dark brown, T4 tipped white on inner web, T5 with white distal third of inner web, T6 white except for base of inner web (white on outer tail conspicuous in flight); whitish to pale buff below, fine dark brown streaks on side of throat, broad blackish streaks on breast, streaks longer and finer on flanks, belly side and undertail-coverts; underwing-coverts and axillaries greyish-buff, streaked darker, tinged bright yellow on carpal; iris brown; bill dark brown above, lower mandible horn-coloured; legs light flesh-brown. Sexes alike. Juvenile is paler than adult, and more spotted above. Race *stygium* is darker above than nominate, has whiter ground colour of underparts, darker breast and flank streaking. Voice. Generally silent. Song loud, high-pitched, rich and melodious, with whistled phrases, rather like that



of Common Wren (*Troglodytes troglodytes*), sometimes given in short bursts, sometimes in long continuous series of forcefully repeated phrases interspersed with long vibrant trills.
Habitat. Rocky wooded hillsides and grassy mountain slopes with rock outcrops and scattered trees and bushes; in Zambia, Malawi and Zimbabwe mainly in areas of *Brachystegia* woodland with rocks beneath; miombo woodland with rocks in Angola. Mostly to 2000 m, but to 2200 m in E Zimbabwe; mainly 1000-1250 m in Malawi, but down to 800 m in extreme S (Mulanje); occurs as low as 150 m in coastal hinterland of NE South Africa.
Food and Feeding. Arthropods; grasshoppers (Orthoptera) recorded. Forages on ground among and over rocks. Often perches in trees.
Breeding. Laying in Nov in Tanzania, Sept-Oct in Malawi and Mozambique, and Sept-Jan in Zimbabwe and South Africa; birds in breeding condition in Nov-Dec in Angola and in Nov in Zambia. Monogamous; territorial. Nest a cup of grass and leaves, lined with finer grasses and rootlets, placed on ground, often near tussock or against rock. Clutch 2-3 eggs, occasionally 1, average of 14 clutches 2·8; incubation and fledging periods, and roles of sexes, unknown.
Movements. Resident and migratory. Tropical populations probably largely sedentary, although some altitudinal movements may occur. Seasonal influxes into S Mozambique and E South Africa (NE KwaZulu-Natal) thought to involve migrants from farther S. Individuals exhibiting features of nominate race (breeding in Northern Province of South Africa) have been found in E highlands of Zimbabwe.
Status and Conservation. Not globally threatened. Widespread. Locally distributed and generally scarce in Tanzania and SE Kenya; locally common in Angola and Botswana and in other parts of range, but generally restricted by habitat. No evidence of any decline, but conservation of broadleaf woodlands, especially of *Brachystegia* miombo woodland in Zimbabwe, is essential. Fortunately, rocky hills where it occurs are largely unsuitable for agriculture.
Bibliography. Benson & Benson (1977), Benson *et al.* (1971), Campbell (1989), Clancey (1952a, 1959a, 1964b, 1968b, 1979, 1984d, 1996), Dean (2000), Fuggles-Couchman (1986), Ginn *et al.* (1989), Godfrey (1932), Hanmer & Chadder (1993), Harrison *et al.* (1997), Hickling (1983), Keith *et al.* (1992), Lawson (1965a), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993a), Newman (1970), Parker (1999), Pedersen (2000), Pedersen & Herroelen (1998), Penry (1994), Roberts (1925), Short *et al.* (1990), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Smart (1999), Snell (1963b), Stevenson & Fanshawe (2002), Steyn (1996), Stjernstedt (2004), Stutterheim (1978), Swynnerton (1911), Tarboton (2001), Terblanche (1997), Vernon (1973, 1985), Voelker (1999c), Weghe (1993), Williams (1997).

21. **Yellow-tufted Pipit**

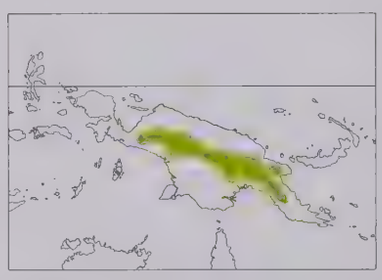
Anthus crenatus

French: Pipit des rochers **German**: Klippenpieper **Spanish**: Bisbita Roquero
Other common names: Rock Pipit(!), African Rock Pipit, Large Yellow-tufted Pipit

Taxonomy. *Anthus crenatus* Finsch and Hartlaub, 1870, near Cape Town, South Africa.
Was previously sometimes thought to form a superspecies with *A. lineiventris*, but the two species differ widely in plumage characters and ecology. Monotypic.
Distribution. South Africa from S & E Northern Cape E in mountains to Mpumalanga, W Swaziland and Lesotho (Drakensberg); also, isolated population in NC Northern Cape (lower R Orange).

Descriptive notes. 17-18 cm; 29-32·5 g. Large, stocky, plain-backed pipit with heavy bill and legs, distinctive yellow edgings on wings. Has prominent buffish supercilium extending behind eye, olive-brown lores and ear-coverts with fine buff streaking, indistinct narrow dark brown malar stripe; plain olive-brown above, slight dark streaking on top of head, greyer side of neck; wings brown, yellowish-green edges of primaries, secondaries and alula, olive-green edges of tertials and greater wing-coverts; tail dark brown with narrow yellowish-green edging, outermost rectrix with outer edge pale and inner web tipped whitish; chin and throat whitish, rest of underparts rich buff, indistinctly streaked brown on breast, dark brown undertail-coverts broadly tipped buff; underwing-coverts and axillaries buff, broadly tipped yellowish-green; iris hazel; bill dark brown, yellowish basal half of lower mandible; legs pale brown. Sexes alike. Juvenile undescribed. VOICE. Song, from perch or in flight, a series of sweet disyllabic phrases repeated several times, second note rather trilled and falling in pitch, "whee-tsreeee, whee-tsreeee"; also a slower, more quavering "whee-pr-rreeu".
Habitat. Mountains and karroid terrain (kopjes and dry stony hills), mainly above 1000 m, in S & W of range; in E, alpine grassland with rock outcrops and boulders, to 3000 m.
Food and Feeding. Diet little known. Recorded items include spiders (Araneae), grasshoppers (Orthoptera) and grass seeds (Gramineae). Forages on the ground, running among stones or creeping in grass, pecking at invertebrates. Usually singly or in pairs.
Breeding. Few records. Laying during summer rains in Oct-Mar, mainly Nov-Jan; once in Aug in SW (winter-rainfall area). Monogamous; territorial. Male sings from rock perch, in upright posture with bill pointing up, sometimes in aerial display. Nest a cup of grass and roots, lined with finer grasses, built on ground under grass tuft, by rock or under overhanging rock on hillside. Clutch 3-4 eggs; incubation period at least 12-13 days; chicks fed by both parents, nestling period at least 11 days; injury-feigning display by adult observed.
Movements. None known; apparent lack of seasonal gregariousness suggests strictly sedentary lifestyle.
Status and Conservation. Not globally threatened. Widely distributed and fairly common in suitable habitat; especially common in Lesotho, where reported as being one of the commoner terrestrial passerines. Apparent decline has occurred in SW of range, but the species is probably not under any threat as its habitat lies above the altitudinal and rainfall limits of crop agriculture. Grazing and seasonal burning of grassland may affect some populations.
Bibliography. Allan & Harris (1984), Allan *et al.* (1997), Bonde (1993), Burger (1990), Campbell (1989), Clancey (1964b, 1990a, 1990b), Dean & Siegfried (1997), Ginn *et al.* (1989), Godfrey (1934), Grobler (1986), Harrison *et al.* (1997), Keith *et al.* (1992), Kok (1996), Kriek *et al.* (1995), Mackworth-Praed & Grant (1963), Maclean (1993a), Martin, H. & Pepler (1997), Martin, R. & Pepler (1999), Martin, R. *et al.* (1985), Newman (1996), Nuttall (1996, 1997), Osborne & Tiggar (1990), du Plessis (1990), Porter (1986), Quickelberge (1972b), Siegfried (1992), Sinclair & Hockey (1996), Sinclair *et al.* (1993), de Swardt (2002), Tarboton (2001), Voelker (1999a, 1999b, 1999c), Wade (1994).

PLATE 73 ➤

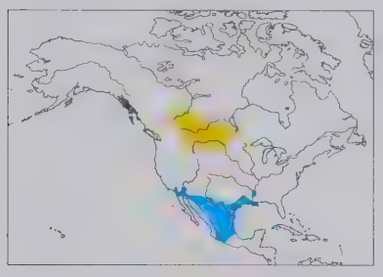


22. New Guinea Pipit

Anthus gutturalis

French: Pipit de Nouvelle-Guinée **German**: Papuapieper **Spanish**: Bisbita Papúa
Other common names: Alpine Pipit, Mountain Pipit(!)

Taxonomy. *Anthus gutturalis* De Vis, 1894, Mount Maneao, south-east New Guinea.
Three subspecies recognized.
Subspecies and Distribution.
A. g. wollastoni Ogilvie-Grant, 1913 - WC New Guinea.
A. g. rhododendri Mayr, 1931- EC New Guinea (in C highlands and Huon Peninsula).
A. g. gutturalis De Vis, 1894 - SE New Guinea.
Descriptive notes. 17-5-18 cm. Large pipit with strong facial pattern. Nominate race has dark brown lores, contrasting creamy supercilium and lower eyelid (giving spectacled appearance), brown ear-coverts; forehead whitish, crown, head side and upperparts blackish-brown, buffy olive-brown feather edgings giving streaked appearance, rump plainer olive-brown to buffy; wing feathers dark brown, edged buffish olive-brown; tail dark brown, edged grey, T5 tipped white, T6 brownish-white to buffy; throat to upper breast white to pale buff, rest of underparts buffy or pale brown, blackish-brown stripe or patch on side of throat and lower neck; iris dark brown; bill black; legs dark horn or pinkish. Sexes alike. Juvenile has blackish-brown streaks below. Race *rhododendri* is slightly smaller than nominate, and has greener upperparts and darker underparts; *wollastoni* has somewhat brighter plumage, but black at side of throat reduced to broken streaks or absent. Voice. Song, often in flight low over ground, described as several high, thin, clear notes each repeated several times before a new note, running into a trill, or a lower coarser trill and various subdued musical calls and whistles. Call faint and high-pitched "tsip" or "tsee", or "tsee tsee tsee"; also subdued musical notes and whistles.
Habitat. Alpine grassland above the tree-line on the highest mountains, between 3200 m and 4500 m, occasionally down to 2500 m. Prefers short grass, often near cover of shrubs.



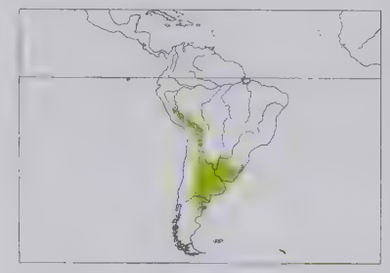
Food and Feeding. Mainly small insects and their larvae, and other arthropods; grass seeds, berries and green herbaceous matter also recorded. Forages on the ground, moving with a "waddling" gait. Sometimes up to ten individuals together. When alarmed, flies to a vantage point such as rock, bush or tree, up to 12 m away, at forest edge. Frequently holds the bill upwards at 45-degree angle.
Breeding. Single nestlings found in latter part of wet season, in Apr, Sept and Oct. Nest a cup of fine grass, placed on steep bank. No other information.
Movements. Resident; no evidence of descent to lower elevations in winter.
Status and Conservation. Not globally threatened. Restricted-range species: present in Adelbert and Huon Ranges EBA and Central Papuan Mountains EBA. No information on current status. Described as common in late 1960s and 1970s; no reason to suppose that any changes in its habitat or population level have taken place since then.
Bibliography. Andrew (1992), Beehler (1978), Beehler *et al.* (1986), Coates (1990, 2001), Coles (1976), Diamond (1972), Mayr (1941), Rand & Gilliard (1967), Sujatnika *et al.* (1995), Strange (2001).

23. Sprague's Pipit

Anthus spragueii

French: Pipit de Sprague **German**: Prärieпieper **Spanish**: Bisbita Llanero

Taxonomy. *Alauda Spragueii* Audubon, 1844, near Fort Union, North Dakota, USA. Molecular-genetic analyses suggest possible close relationship with *A. furcatus*, *A. hellmayri* and *A. bogotensis*. May form a clade with those and with *A. lutescens*, *A. correndera* and *A. antarcticus*. Monotypic.
Distribution. Breeds in S Canada (C & SE Alberta, C & S Saskatchewan, SW Manitoba) and N USA (N & C Montana, North Dakota, N South Dakota, NW Minnesota). Winters from S USA S to C Mexico.



Descriptive notes. 15-17 cm; c. 25 g. Rather small, highly secretive pipit with strongly streaked upperparts. Has indistinct pale buffish supercilium, pale buffy grey-brown ear-coverts indistinctly streaked, faint dark malar stripe; above, pale grey-brown with buff to rufous tinge, streaked blackish-brown, streaks particularly prominent on forehead to mantle, paler feather tips forming two stripes on side of mantle (when plumage fresh); wings dark brownish, wing-coverts tipped whitish (two wingbars); tail dark brownish, T4 with white edge of outer web, T5 with mostly white outer web and long white wedge on inner web, T6 with outer and most of inner web white; throat pale buffish, breast and flanks warm buffish, breast and occasionally rear flanks streaked grey-brown, rest of underparts pale buffish-white; iris dark brown; upper mandible blackish, lower mandible pale pinkish with blackish tip; legs pale pinkish or pale brownish-yellow. Sexes alike. Juvenile has more obvious streaking on head and nape, pale feather edgings above giving scalloped appearance, more obvious white wingbars, whiter underparts with bolder and more rounded breast streaks. Voice. Song, almost always in flight, a musical series of thin, jingling phrases on descending scale, "ching-a-ring-a-ring-a ring-a". Calls an explosive squeaky "sweep" or "speep", often double notes, or, when flushed, "speep-beep-beep".
Habitat. Grassland and weedy fields on plains and prairies during summer; in non-breeding season, temperate grassland at up to 2500 m. Often forages in weed-grown fields during migration.
Food and Feeding. Small invertebrates, mainly insects such as grasshoppers and crickets (Orthoptera), ants (Hymenoptera), beetles (Coleoptera), bugs (Hemiptera) and larval and adult lepidopterans; also weed seeds. Forages on the ground, usually well concealed, rarely in open. Usually singly or in pairs; occasionally small groups outside breeding season.
Breeding. Laying in late May and Jun. Displaying male ascends to over 100 m, circles and sings with tail spread, then plunges, wings closed, towards ground; female may fly up to meet him. Nest built of grass, in hollow in ground or in grass tuft. Clutch 3-7 eggs, usually 4-5; incubation by female alone, period 13 days; fledging period 10-11 days. Nest success often poor, as low as 24% in study in S Saskatchewan (Canada); parasitized by Brown-headed Cowbird (*Molothrus ater*).
Movements. Migratory. Leaves breeding grounds from late Sept, flying mostly through C USA; spends non-breeding season in S USA (S from S Arizona, Texas, S Louisiana and NW Mississippi) and N & C Mexico (mainly Mexican Plateau and Gulf-Caribbean slope); returns N in late Mar and through Apr, arrival on breeding grounds in May in N. Vagrants recorded in most US states.
Status and Conservation. VULNERABLE. Population has declined rapidly. Probably fairly common in some parts of range but uncommon to rare in others; in USA, breeds only irregularly in South Dakota and rare in NW Minnesota; in Canada, occasional breeding recorded outside main range, in S British Columbia, possibly also in W Ontario. Current population estimates vary; certainly more than 10,000 adults, but some estimates give far higher figure. Since 1900, c. 75% of Canadian prairies thought to have been lost to agricultural changes, and significant declines in this species' numbers probably occurred in late 19th and early 20th centuries. Since 1970, rapid population reduction of 4-7% annually; rates of decline have decreased in USA but increased in Canada (equivalent of 53% decline in 10 years since 1975). Although most of the prairie habitat is unprotected, large areas are in military reserves, national parks and on Prairie Farm Rehabilitation lands. Threats include loss of and degradation of both breeding and non-breeding habitats, mainly through conversion of prairies to seeded pasture, hayfields and cropland, and intensive grazing; overgrazing, burning and hay-cutting adversely affect habitats and cause nest losses. Impacts of grazing and burning, however, variable; in particular, burning is considered a preferred management technique as it reduces the number of woody plants, and, although having a negative impact in the first year, it has positive effects in subsequent years. Introduction of alien plant species also has negative effect on breeding densities of this species. In addition, this is one of the North American grassland species considered most vulnerable to global warming; models project that it could potentially be extirpated from most of its current range in the USA and S Canada.

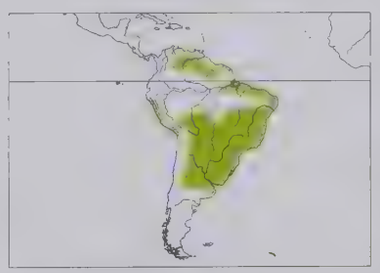
24. Short-billed Pipit

Anthus furcatus

French: Pipit à plastron **German**: Weißbauchpieper **Spanish**: Bisbita Piquicorto

Taxonomy. *Anthus furcatus* d'Orbigny and Lafresnaye, 1837, Carmen, Río Negro, Patagonia, Argentina.
Molecular-genetic analyses suggest possible close relationship with *A. spragueii*, *A. hellmayri* and *A. bogotensis*. May form a clade with those and with *A. lutescens*, *A. correndera*, *A. antarcticus*. Two subspecies recognized.
Subspecies and Distribution.
A. f. brevirostris Taczanowski, 1875 - C Peru S to W Bolivia and NW Argentina (Jujuy).
A. f. furcatus d'Orbigny & Lafresnaye, 1837 - lowlands of Argentina (Tucumán S to N Chubut) E to extreme SE Brazil and Uruguay.



Descriptive notes. 14-14·5 cm; 20 g. Smallish, streaked pipit with relatively short, deep-based bill. Has whitish eyering and supercilium, prominent black malar stripe; above, streaked and mottled blackish-brown and buffy brown, appearing scaled; wings dusky, primaries narrowly edged white, secondaries, tertials and wing-coverts edged buffy (two pale wingbars); tail dusky, outer two feather pairs white or whitish; whitish below, breast and flanks strongly tinged ochraceous, upper breast with well-marked area of blackish streaking (more greyish and less boldly streaked below when plumage worn); underwing-coverts white; iris brown; bill dark; legs pale pinkish-buff, somewhat curved hind claw of medium length (10 mm). Sexes alike. Juvenile resembles adult, but has broad creamy edgings on upperparts. Race *brevirostris* generally buffier, less greyish, with longer, bolder streaks on flanks (often concealed by wings). Voice. Song, uttered incessantly in flight, is musical and repetitive, "gleeeeeeeu-teedeleh-tleetleetlee" or variation.
Habitat. Short grass by lakes, in pastures, and on rolling hills with mix of bunch-grass and short grass in *puna* zone, to 4300 m; generally in more arid country than other Andean pipits. At lower altitudes, occurs on temperate grassland.
Food and Feeding. Small insects and other invertebrates, probably also seeds; no details available. Forages while walking on the ground, as other pipits; picks food items from surface. Associates with *A. correndera*; unlike that species, does not wag tail. Occurs singly or in pairs in breeding season; in flocks at other times.
Breeding. Few data. Male in nuptial flight hovers at 60-80 m in air for 10-30 minutes or more, diving during each song bout, rarely alighting on trees. Cup-nest of grasses, in depression on ground. Clutch up to 4 eggs. No other information available.
Movements. Poorly known. May undertake some local movements, as it forms flocks outside breeding season; possibly altitudinal movements in Andes (race *brevirostris*). Some longer-distance movements occur, as individuals appear in Paraguay during non-breeding season.
Status and Conservation. Not globally threatened. Status uncertain; described variously as fairly common and as uncommon to locally common. In Argentina, reportedly most numerous in Patagonian steppes of Río Negro; much less numerous than *A. correndera* in *pampas* of Buenos Aires. No particular threats identified.
Bibliography. Andors & Vuilleumier (1995), Bond (1956a), Canevari *et al.* (1991), Chebez *et al.* (1999), Couve & Vidal-Ojeda (2003), Fjeldså & Krabbe (1990), Hayes (1995), Hayes *et al.* (1994), Hellmayr (1935), Hennessey, Herzog & Sagot (2003), Isacch & Martínez (2001), Johnson (1967), Klimaitis & Moschione (1987), Meyer de Schauensee (1982), Mouchard (1998), Narosky & Di Giacomo (1993), Ridgely & Tudor (1989), Rocha & Peñaranda (1995), Roe & Rees (1979), Salvador (1988), Sick (1993), Stotz *et al.* (1996), Vickery *et al.* (2003), Vuilleumier (1985), Zimmer (1930, 1953).

25. Yellowish Pipit

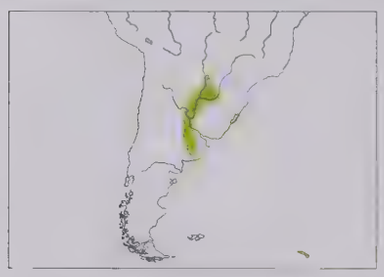
Anthus lutescens

French: Pipit jaunâtre **German**: Savannenpieper **Spanish**: Bisbita Amarillento

Taxonomy. *Anthus lutescens* Pucheran, 1855, vicinity of Rio de Janeiro, Brazil.
Relationships uncertain; may form a clade with *A. spragueii*, *A. furcatus*, *A. correndera*, *A. antarcticus*, *A. hellmayri* and *A. bogotensis*. Form "*A. chii*" might be referable to present species, but best considered unidentifiable. Three subspecies recognized.
Subspecies and Distribution.
A. l. parvus Lawrence, 1865 - Pacific slope in W Panama.
A. l. lutescens Pucheran, 1855 - NE Colombia, Venezuela (except N & S), the Guianas, and lowlands from E Bolivia and N, C & E Brazil S to Argentina (S to La Pampa and SE Buenos Aires) and Uruguay.
A. l. peruvianus Nicholson, 1878 - coastal Peru (S from Trujillo) S to extreme N Chile (Arica).

Descriptive notes. 13 cm; 13-18 g. Very small, rather slender pipit with yellowish underparts, relatively short tail. Nominate race has narrow white eyering, very indistinct pale supercilium; dark brown above, buff-brown feather edging giving streaked appearance, speckling on side of neck; remiges blackish-brown, edged buff, pale tips of wing-coverts (two pale wingbars); tail blackish-brown, T5 white apart from dark inner edge of inner web, T6 has white or pale brown outer web and white inner web; buffy to yellowish-white below, dark brown streaks across breast (forming band) and on upper flanks; iris dark; bill dark; legs pale. Distinguished from almost all other pipits by small size and yellowish underparts; from *A. nattereri* by smaller size, less golden tone below. Sexes alike. Juvenile undescribed. Race *peruvianus* is slightly larger than nominate, paler above, feather edgings greyish, wing-covert tips more whitish and less buffy, whiter and less buffy yellow below; *parvus* is small, has feather edgings above more cinnamon-

On following pages: 26. Chaco Pipit (*Anthus chacoensis*); 27. Correndera Pipit (*Anthus correndera*); 28. South Georgia Pipit (*Anthus antarcticus*); 29. Ochre-breasted Pipit (*Anthus nattereri*); 30. Hellmayr's Pipit (*Anthus hellmayri*); 31. Paramo Pipit (*Anthus bogotensis*).



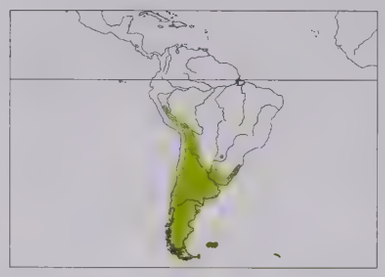
buff, is more yellowish with less extensive streaking below. Voice. Song, usually in flight, a series of "tsit" notes during ascent followed by long slurred "dzeeeeeeeeeeeu" during slow gliding descent, has been likened to sizzle sound of fireworks being set off. Call a short "tsitsirrit", also "wisst".
Habitat. Grassland and adjoining bare areas. Found in variety of open habitats, from tropical damp, often seasonally wet, short grassland to pastures and agricultural land, often near rivers, lakes and marshes; seems to prefer very short grass. Lowlands, to c. 1300 m; in Venezuela, below 200 m N of R Orinoco.
Food and Feeding. Small insects, probably also seeds; no detailed information. Forages by walking and running in short grass; when disturbed, often flies up high and moves far away.
Breeding. Season Jan-Jun, also Sept, in Panama; recorded in May-Jun and Sept-Oct in Venezuela. Monogamous; territorial, but often loosely colonial, with 15-20 birds in close proximity. In display-flight, male rises 10-20 m in air, rarely to 50 m, makes series of steep climbs and descents, then glides slowly in straight line down to ground. Nest described as oven-like, constructed of grasses and other soft vegetation, on ground in short grass. Clutch 2-4 eggs. No further information.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Widespread, and locally fairly common to common in much of range. Not considered likely to be at any risk.
Bibliography. dos Anjos *et al.* (1997), Anon. (1998a), Araya & Chester (1993), Brace *et al.* (1997), Canevari *et al.* (1991), Chebez *et al.* (1999), Delgado (1985), Eisenmann (1955), Fraga & Clark (1999), Friedmann & Smith (1950), Haverschmidt & Mees (1994), Hayes (1995), Hellmayr (1932, 1935), Hilty (2003), Hilty & Brown (1986), Jaramillo (2003), Johnson (1967), Narosky & Di Giacomo (1993), Parker & Goerck (1997), Ridgely & Gwynne (1989), Ridgely & Tudor (1989), do Rosário (1996), Schubart *et al.* (1965), Sick (1993), da Silva *et al.* (1997), Silveira (1998), Stotz *et al.* (1996), Straneck (1987), Tostain (1980), Tostain *et al.* (1992), Vickery *et al.* (2003), Wetmore *et al.* (1984), Zimmer (1953).

26. Chaco Pipit

Anthus chacoensis

French: Pipit du chaco **German**: Chacopieper **Spanish**: Bisbita Chaqueño

Taxonomy. *Anthus chii chacoensis* J. T. Zimmer, 1952, Avia Terai, Chaco, Argentina.
Relationships unclear; appears to be close to *A. lutescens*. Monotypic.
Distribution. Lowlands from Paraguay (S from Concepción) S to EC Argentina (S to SC Buenos Aires).



Descriptive notes. 13 cm. Very small, streaked pipit. Has pale areas around eye, short dark moustachial streak, faint thin dark malar stripe; dark brown above, greyish edges of feathers giving streaked appearance; wings blackish-brown, edged pale buffish; tail dark brown, outer rectrix mostly white; white below, dark spots on breast, dark streaks on flanks; iris dark; bill dark, pinkish base of lower mandible; legs pinkish. Distinguished from closely similar *A. lutescens* by streaks above being whiter, less buffy, no trace of yellow on underparts, more pronounced streaks on flanks; in the hand, also shorter hind claw, less white on tail. Sexes alike. Juvenile undescribed. Voice. Song, in flight, long protracted series of more than 50 syllables, e.g. "clicliclicliclidlidli... dlewdlew... dleeddleed... leecleeclee... cliclicli".
Habitat. Lowland grassland, including pastures. Prefers open areas with grass no taller than 50 cm.
Food and Feeding. Diet unknown. Forages on the ground, in typical pipit fashion.
Breeding. In song flight, male rises to 60-80 m, lower when winds strong, occasionally drops short distance before rising again; display can last for over 1 hour. No other information.
Movements. Partial migrant; S population migrates N to SE Paraguay and N Argentina.
Status and Conservation. Not globally threatened. Fairly common. Formerly regarded as a high conservation priority and high research priority, as it was so poorly known and apparently had a restricted distribution; there were concerns about a possible decline. Recent work in Argentina, however, suggests that it is more widespread than was previously thought and that it has probably been overlooked. Research needed on its ecology and breeding behaviour.
Bibliography. Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Collar & Andrew (1988), Collar *et al.* (1994), Fjeldså & Krabbe (1990), Hayes (1995), Isacch *et al.* (2003), Lowen *et al.* (1996), Narosky & Di Giacomo (1993), Narosky & Yzurieta (1993), Nellar (1993), de la Peña (1997), Ridgely & Tudor (1989), Short (1975, 1976), Stotz *et al.* (1996), Straneck (1987), Vickery *et al.* (2003).

27. Correndera Pipit

Anthus correndera

French: Pipit correndera **German**: Correnderapieper **Spanish**: Bisbita Correndera

Taxonomy. *Anthus correndera* Vieillot, 1818, Paraguay. Probably closest to *A. antarcticus*; the two may be part of a clade that also contains *A. spragueii*, *A. furcatus*, *A. lutescens*, *A. hellmayri* and *A. bogotensis*. Recent DNA work suggests that nominate race and *catamarcae* may represent a separate species, or indeed two separate species. Races appear to intergrade. Proposed race *phillipsi* (Port Stanley, in Falkland Is) synonymized with *grayi*. Five subspecies tentatively recognized.
Subspecies and Distribution.
A. c. calcaratus Taczanowski, 1875 - mountains of Peru.
A. c. catamarcae Hellmayr, 1921 - N Chile (E Antofagasta), SW Bolivia and NW Argentina (Catamarca).
A. c. correndera Vieillot, 1818 - S Paraguay, N Argentina, Uruguay and extreme SE Brazil (Rio Grande do Sul).
A. c. chilensis (Lesson, 1839) - Chile (S from Atacama) and S Argentina S to Tierra del Fuego.
A. c. grayi Bonaparte, 1850 - Falkland Is.
Descriptive notes. 14-16 cm; 15-26·5 g (*grayi*), two males 20·2 g and 20·3 g (*correndera*). Small, well-marked pipit with long bill and flat head. Nominate race has whitish supercilium and eyering, narrow blackish moustachial and malar stripes; upperparts dusky, heavily streaked cinnamon-buff, two longitudinal white stripes on each side of mantle; wings dusky, primaries edged white, wing-coverts edged buffy white (two wingbars); tail dusky, outer two feather pairs mostly white to whitish; buffy white to whitish below, bold black spots across breast and prominent streaking on flanks; iris dark; bill dark, paler base of lower mandible; legs brown to pinkish-brown, hind claw almost straight. Sexes alike. Juvenile has supercilium tinged yellow, feathers of upperparts edged whitish, primaries edged yellow, wingbars white, buffer below. Races differ in amount of white in tail, and colour of upperparts and underparts (extent of cinnamon): *chilensis* is darker and more buffy than nominate, mantle streaks pale buff, rump tinged rufous, has less dense streaking on breast but streaks extend to upper belly, less white in tail (confined to outermost feather and shaft of adjacent feather); *catamarcae* is darker above with more rufous on rump than previous, and has wing, bill and tarsus longer; *calcaratus* is much darker than nominate, upperparts tinged cinnamon, rump rufous, buff below; *grayi* is larger than nominate, with stronger bill, smaller markings on breast. Voice. Song, in flight or sometimes from perch, a repetition of simple phrases, e.g. "glishaw-gleeeer, glishaw-cleeeer, glishaw-gleeeer", with last note drawled, or "tzi ti tie tzi ti trrrr", with final trill prolonged (during glide); also, from perch, short varied phrases repeated up to five times. Flight call a harsh "trrrit", "srit" or "tsrrr".

Habitat. In N (nominate race and *calcaratus*), *puna* grassland on arid plateaux, also pastures and agricultural land, and in wetter situations such as bogs and lakeshores with short grass and scattered clumps of rushes; 2500-4450 m. Elsewhere, found in grassland, wetland edges and Patagonian steppe, from sea-level to c. 1250 m; prefers large areas of coarse white grass in wet areas in Falklands (*grayi*). Occurs frequently on grassy roadsides. Where it overlaps with *A. furcatus*, uses lusher areas with taller grass than those preferred by latter.
Food and Feeding. Poorly known. Adult and larval insects and other invertebrates, probably also seeds. Chicks fed with small worms and lepidopterans in Falklands (*grayi*). Forages on ground, walking and running in typical pipit fashion.
Breeding. Jun-Dec; possibly throughout year in C Peru (Junín); late Sept to Dec in Falklands; often two broods. In song flight, male rises quickly to 20-40 m, then hovers while singing, often glides downwards and rises again several times. Nest a grass cup, lined with finer material and hair, well concealed in a depression on ground. Clutch 2-4 eggs; incubation and fledging periods apparently not documented.
Movements. Resident and partial migrant. Some in C & S parts of range (*chilensis*) remain in breeding area throughout year, although many move N after breeding; those in extreme S migrate N in Apr and return in Sept; nominate race also recorded as non-breeding visitor in SE Brazil (N to São Paulo).
Status and Conservation. Not globally threatened. Common to fairly common and widespread throughout range; very numerous on the *pampas* of Buenos Aires (E Argentina). Common in Falkland Is (race *grayi*), estimated 8000-15,000 pairs in 1983-1993. Not likely to be at any risk in the foreseeable future in most of range. Introduced cats and rats (*Rattus*) represent a threat in Falklands, where grass-burning also a problem.
Bibliography. dos Anjos *et al.* (1997), Araya & Chester (1993), Barrows (1883), Bond (1956a), Bornschein *et al.* (1997), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Couve & Vidal-Ojeda (2003), Fjeldså & Krabbe (1990), Hall *et al.* (2002), Harris (1998), Hayes (1995), Hayes *et al.* (1994), Hellmayr (1932, 1935), Humphrey *et al.* (1970), Isacch & Martínez (2001), Isacch *et al.* (2003), Jaramillo (2003), Johnson (1967), Klimaitis & Moschione (1987), Landbeck (1877), Narosky & Di Giacomo (1993), Navas & Bó (2000), Parmelee & Rasmussen (1994), Ridgely & Tudor (1989), Roe & Rees (1979), do Rosário (1996), Shirihai (2003), Sick (1993), Stotz *et al.* (1996), Voelker (1999a, 1999b), Vuilleumier (1985), Woods (1988), Woods & Woods (1997), Zimmer (1953).

28. South Georgia Pipit

Anthus antarcticus

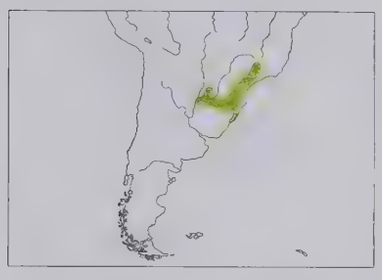
French: Pipit antarctique **German**: Riesenpieper **Spanish**: Bisbita de Georgia del Sur
Other common names: Subantarctic Pipit

Taxonomy. *Anthus antarcticus* Cabanis, 1884, South Georgia.
May be closely related to, and possibly have evolved from, *A. correndera*; the two may belong to a clade that also includes *A. spragueii*, *A. furcatus*, *A. lutescens*, *A. hellmayri* and *A. bogotensis*. Monotypic.
Distribution. South Georgia (mainland and offshore islets), in S Atlantic Ocean.

Descriptive notes. 16·5 cm. Has indistinct buffish supercilium and area around eye, more prominent blackish moustachial and malar stripes; dark brown above, rufous or fawn-white feather edges giving heavily streaked appearance, indistinct pale lines on mantle side; wing feathers edged pale, wing-coverts with pale tips (indistinct wingbar on median coverts); tail blackish-brown, outer rectrix mostly greyish-white; throat whitish, underparts whitish, breast, belly and flanks usually washed buff, with heavy brown streaks, belly centre less streaked; iris dark brown; bill blackish, reddish base; legs greyish to flesh-brown, hind claw rather long. Sexes alike. Juvenile is generally more buff than adult, especially below. Voice. Song, in flight, soft twittering phrases and high-pitched series, up to several minutes in duration, described as resembling song of a *Motacilla* or of Song Sparrow (*Melospiza melodia*) but longer, and softer in tone than latter's; also a shorter song, with longer intervals, from ground. Quiet soft notes or sharper "tzip" when flushed.
Habitat. Tussac (*Poa flabellata*) grassland, especially by streams and inland pools, and rocky shores; at and near sea-level. Mainly along ice-free shorelines during austral winter.
Food and Feeding. Small arthropods, such as adult and nymphal springtails (Collembola), beetles (Coleoptera), flies (Diptera) and spiders (Araneae). Springtails trapped in small freshwater pools by surface tension a favoured food in spring; feeds extensively on marine invertebrates along shoreline and around tidal pools, especially when grass areas snow-covered during winter. Uses thick grass as cover when foraging; walks or runs a short distance, stops, flicks tail, runs again. Picks food items from grass or from algae.
Breeding. Breeds mid Nov-Jan/Feb; frequently double-brooded. Male performs display-flight. Nest a deep, bulky cup of fine roots and dry grass, lined with feathers, partly domed, built ground within grass tussock; also reported as placed in rock crevice on mainland. Clutch usually 3-4 eggs, sometimes 5; incubation and fledging periods not documented. Winter survival of juveniles low. Occasionally preyed on by Brown Skua (*Catharacta antarctica*) of race *lonnbergi*.
Movements. Resident; most move to offshore islets to breed.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Not uncommon; current population estimated at 3000-4000 pairs. Has been largely exterminated from the mainland by brown rats (*Rattus norvegicus*), and breeds only in a few areas enclosed by sea-level glaciers on S side of island, where rats absent; breeding pairs now largely confined to c. 20 rat-free offshore islets, e.g. 150-200 pairs on Bird I, and numerous on Prion I (e.g. 6 pairs in c. 0·5 km on a tussocky hillside). Rapid increase in numbers of Antarctic fur seals (*Arctocephalus gazella*) at South Georgia (where 95% of world population now breeds) has resulted in destruction of more

than 60% of the tussac grass habitat in certain areas (mainly Bird I and NW extremity of main island), as females and pups wander inland to rest in summer; grasses along streambanks and in meadows also squashed by fur seals moving between coast and inland haul-out areas. Although destruction of vegetation may have had some detrimental effects on this pipit, which depends on tussac grass for nesting sites, one researcher noted no change in the species' numbers on Bird I during nine years in 1990s; he suggested that damage to grass might have caused redistribution of the species, rather than any reduction in its numbers. Brown rats, combined with recession of glaciers (allowing further spread by this predator), believed to pose main threats.

Bibliography. Atkinson (1985), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Croxall (1987), Headland (1984), Hellmayr (1935), Jaramillo (2003), McIntosh & Walton (2000), Prince & Croxall (1983), Prince & Poncet (1996), Pye & Bonner (1980), Reeves *et al.* (1992), Ridgely & Tudor (1989), Shirihai (2003), Stattersfield & Capper (2000).



29. Ochre-breasted Pipit

Anthus nattereri

French: Pipit ocré **German**: Ockerbrustpieper **Spanish**: Bisbita Ocre

Taxonomy. *Anthus nattereri* P. L. Sclater, 1878, Rio Verde, São Paulo, Brazil. Monotypic.

Distribution. S Paraguay, NE Argentina (Corrientes) and SE Brazil (Minas Gerais S to Rio Grande do Sul).

Descriptive notes. 13·5-15 cm. Rather small pipit with distinctive plumage. Has yellow-buff supercilium streaked black, black spot on cheek, thin dark moustachial stripe; blackish-brown above, including wings, with bright buff or golden ochraceous-yellow feather edgings giving boldly streaked blackish appearance; rump less streaked, and more rufous or golden-buff; tail dark brown, feathers pointed, T4 paler and tipped white, T6 pale brownish-white with dark brown wedge on proximal part of inner web, T5 similar but has more dark brown; throat creamy; breast golden-buff to orange, streaked brown, flanks rufous-buff, streaked brown, belly buffy white; iris dark; bill brown, basal two-thirds of lower mandible pale; legs yellow-brown or reddish-brown, long hind claw. Sexes alike. Juvenile not described. Voice. Song, in flight, complex and musical series of notes ending in slurred "eeeeeeeur", followed by several nasal notes on alighting on ground.

Habitat. Dry pastures and fields and rolling *campo* grassland, to 900 m. Has been recorded in breeding season in young eucalypt (*Eucalyptus*) plantation. Appears to show some preference for burnt areas with regenerating short grass (Brazil) or lightly grazed grassland.

Food and Feeding. Little known. Small invertebrates; one stomach contained only insects. Forages on the ground, picking food items.

Breeding. Nest with eggs in Oct; gonadal condition of specimens and recorded song period suggest breeding probably in Sept-Jan. In aerial display, male rises to c. 25 m, hovers while singing, descends rapidly in spiral (still singing). Few other data, all from S of range. Nest a shallow cup of plant stems and grass roots, on ground by grass tussock. One clutch documented, of 4 eggs, incubated by female, role of male not known. Nest parasitism by Shiny Cowbird (*Molothrus bonariensis*) recorded.

Movements. Not well known; studies in SE Brazil (São Paulo) suggest that it is semi-nomadic in response to optimal conditions.

Status and Conservation. VULNERABLE. Scarce and very local. Formerly considered Endangered, but recently found to be more widespread and somewhat less rare than was thought. In Paraguay, surveys in late 1990s revealed the species' presence at 14 sites, with important populations in Misiones and Caazapá and at two sites in Itapúa. In Argentina, was found in Corrientes in 1960s and rediscovered at same locality (now named San Juan Bautista) in Jan 1993. Previously widespread and not uncommon in Brazil, but has declined greatly; recent observations from at least three sites in Minas Gerais, including Serra da Canastra National Park, and one in São Paulo, and a possible observation farther S, in Santa Catarina. The dry natural grasslands that it requires are threatened by agricultural and forestry development; conversion to crops such as sugar cane and soybeans in Brazil, and the planting of alien trees such as eucalypts on grasslands in all three countries in which it occurs, are of major concern, as are the conversion of grassland to reseeded pasture and the use of pesticides. Intensive grazing, over-frequent burning and invasive grasses are additional threats. A critical factor, at least locally, seems to be the species' need for a mosaic of burnt grassland areas; although it initially disappears after fires, it is one of first species to reappear when grass has regenerated, but it cannot tolerate annual burning of habitat. Flooding resulting from the Yacyretá Dam, in Paraguay, is a further problem, and parasitism by Shiny Cowbird may add to the pressures faced by this pipit.

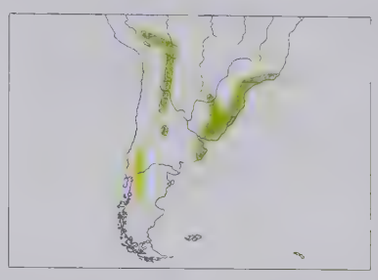
Bibliography. dos Anjos *et al.* (1997), Anon. (1999b), Belton (1985), Canevari *et al.* (1991), Cavalcanti (1999), Chebez (1994), Chebez *et al.* (1999), Clay, Capper *et al.* (1998), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Coutinho (1982), Cracraft (1985), Di Giacomo & Krapovickas (2001), Hayes (1995), Hellmayr (1935), Lowen *et al.* (1996), Meyer de Schauensee (1982), Parker & Willis (1997), Pearman & Abadie (1995), Ridgely & Tudor (1989), do Rosário (1996), Sick (1985, 1993), Silveira (1998), Stattersfield & Capper (2000), Stotz *et al.* (1996), Wege & Long (1995), Willis (1991a), Willis & Oniki (1988c).

30. Hellmayr's Pipit

Anthus hellmayri

French: Pipit de Hellmayr **German**: Hellmayrpieper **Spanish**: Bisbita Pálido

Taxonomy. *Anthus hellmayri* Hartert, 1909, Río Salí, Tucumán, Argentina.



Molecular-genetic analyses suggest possible close relationship with *A. spragueii*, *A. furcatus* and *A. bogotensis*; all may belong to a clade that also includes *A. lutescens*, *A. correndera* and *A. antarcticus*. DNA studies also suggest that nominate race and *brasilianus*, geographically isolated from each other and differing significantly in size, plumage colour and pattern, and voice, may represent two separate species. Race *dabbenei* possibly inseparable from nominate, but also geographically remote. Three subspecies recognized.

Subspecies and Distribution.

A. h. hellmayri Hartert, 1909 - E Andean slopes from SE Peru (Puno) S to NW Argentina (S to Tucumán, also in Sierras de Córdoba).

A. h. dabbenei Hellmayr, 1921 - highlands of S Argentina in Neuquén and W Chubut, also SE Río Negro (Somuncurá Plateau); probably also adjacent S Chile.

A. h. brasilianus Hellmayr, 1921 - SE Brazil (S from Espírito Santo), SE Paraguay, NE & E Argentina (Corrientes, E Buenos Aires) and Uruguay.

Descriptive notes. 14-14·8 cm. Rather small pipit. Nominate race has dusky-streaked whitish supercilium and eyering, small blackish moustachial stripe; pale buff upperparts boldly streaked blackish-brown; wings dusky, primaries and tertials edged whitish, secondaries edged buff (forming patch), wing-coverts edged buff (two wingbars); tail dusky, T5 with small white tip in fresh plumage, T6 mostly buffy white; throat white; underparts buffy white, streaked dusky on breast and flanks; underwing-coverts buffy white; iris dark; bill blackish, paler lower mandible; legs pinkish-flesh. Differs from *A. furcatus* in having streaks on back bolder, breast streaks narrower, streaking on flanks, no prominent malar stripe; from *A. bogotensis* in less buff upperparts with paler streaks, much paler underparts with more extensive and darker streaks. Sexes alike. Juvenile has whitish feather edgings above, is more buff below. Race *dabbenei* is very like nominate, but always has white spot on penultimate tail feather (even when plumage worn); *brasilianus* has edges of all wing feathers tinged cinnamon, underparts also tinged cinnamon. Voice. Song, from perch (fence post, rock) or in air, varied, "zilid zilid zidel-zi, zi arr" or "tu-tee-deée-tu", notes repeated at intervals of 5 seconds. Call "sclip", "tlit", "tjip" or "srip".

Habitat. Grassland; often moist open grassland in *puna* zone in W, to 3600 m (race *dabbenei*) or 3700 m (nominate); in E, dry rocky hillsides and other grassland areas, as well as pastures and agricultural land, to 750 m, locally to 2200 m (*brasilianus*).

Food and Feeding. Data on food preferences lacking. Forages in grassland in manner of other pipits, picking insects from the ground or from short vegetation.

Breeding. Breeds Nov-Jan in Bolivia. Short display-flight, male climbs almost vertically while singing, makes spiralling descent in wide circles with wings held high. No other information.

Movements. S race *dabbenei* migrates N in austral winter. Resident elsewhere.

Status and Conservation. Not globally threatened. Locally uncommon to frequent as a breeding species. Status in Argentina poorly understood; seems to be fairly common in Tucumán, but situation elsewhere uncertain; further study needed. Only three confirmed records in Chile, all in La Araucania; believed to be probably a regular but uncommon breeder there, but clarification required.

Bibliography. dos Anjos *et al.* (1997), Araya & Chester (1993), Bond (1956a), Camperi & Darrieu (1995), Canevari *et al.* (1991), Casañas (1997), Chebez *et al.* (1999), Ferreira de Vasconcelos (2003), Fjeldså & Krabbe (1990), Hellmayr (1932, 1935), Jaramillo (2003), Johnson (1967), Lowen *et al.* (1997), Marín (2004), Narosky & Di Giacomo (1993), Navas & Bó (2000), Nores (1986), Parker & Goerck (1997), Ridgely & Tudor (1989), do Rosário (1996), Salvador (1988), Sick (1993), Silveira (1998), Stotz *et al.* (1996), Voelker (1999a, 1999b), Vuilleumier (1985), Zimmer (1953).

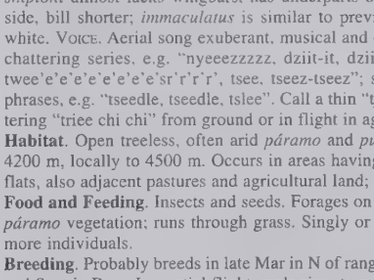
31. Paramo Pipit

Anthus bogotensis

French: Pipit du paramo **German**: Paramopieper **Spanish**: Bisbita Andino

Taxonomy. *Anthus bogotensis* P. L. Sclater, 1855, Santa Fe de Bogotá, Colombia.

Molecular-genetic analyses suggest possible close relationship with *A. spragueii*, *A. furcatus* and *A. hellmayri*; all may belong to a clade that also includes *A. lutescens*, *A. correndera* and *A. antarcticus*. Four subspecies recognized.



Subspecies and Distribution.

A. b. meridae J. T. Zimmer, 1953 - Andes in NW Venezuela (Trujillo, Mérida, N Táchira).

A. b. bogotensis P. L. Sclater, 1855 - NW Venezuela (Páramo de Tamá, in S Táchira) and Andes from Colombia (N & S parts of C range, also E range S to Cundinamarca) S to N Peru (Cajamarca).

A. b. immaculatus Cory, 1916 - NC Peru S to Bolivia (La Paz, Cochabamba).

A. b. shiptoni (Chubb, 1923) - NW Argentina (Tucumán).

Descriptive notes. 15 cm. Rather slender pipit with relatively long bill. Nominate race has faint blackish-streaked buffy supercilium, narrow whitish eyering; above, dusky to cinnamon-brown, boldly streaked blackish and buff; remiges edged buffy brown, wing-coverts dusky with buff tips (two narrow buffy wingbars); tail dusky, outer rectrix with whitish outer web and buffy inner web, adjacent feather with whitish tip; throat light buff, underparts deep buff (greyer when worn), sparse dark streaks on breast and flanks; underwing-coverts buff; iris brown; bill dusky above, pale below; legs pinkish. Sexes alike. Juvenile not described. Race *meridae* has broader buffy wingbars than nominate, tip of T5 buffy, not white; *shiptoni* almost lacks wingbars, has underparts buffy white to white, sometimes unstreaked on side, bill shorter; *immaculatus* is similar to previous, has crown streaks and supercilium buffy white. Voice. Aerial song exuberant, musical and complex, long wheezing note followed by high chattering series, e.g. "nyeeezzzzz, dziit-it, dziit-it, chit-it-it-it-it-it" or "sweet-sweet-sweez-twee'e'e'e'e'e'e'e'sr'r'r'r', tsee, tseez-tseez"; song from perch thinner, simpler, with broken phrases, e.g. "tseedle, tseedle, tslee". Call a thin "tjirp" or "pit-sit" or "chit chit"; sometimes chattering "triee chi chi" from ground or in flight in aggressive encounters.

Habitat. Open treeless, often arid *páramo* and *puna* grassland in upper montane zone, at 2100-4200 m, locally to 4500 m. Occurs in areas having mix of short grass and bunch-grass, bogs and flats, also adjacent pastures and agricultural land; favours flatter areas.

Food and Feeding. Insects and seeds. Forages on the ground in low shrubs and grass, and in low *páramo* vegetation; runs through grass. Singly or in pairs, occasionally in small parties of six or more individuals.

Breeding. Probably breeds in late Mar in N of range; eggs in Dec and young birds reported in May and Sept in Peru. In nuptial flight, male rises to moderate height and makes slow gliding descent. No further data.

Movements. Apparently resident; some seasonal elevational movements may occur.

Status and Conservation. Not globally threatened. Locally common to fairly common; uncommon to locally fairly common in Ecuador. Can be difficult to locate, and may be overlooked. Possibly occurs more widely in Colombian Andes and more continuously in S of range (Bolivia, Argentina).

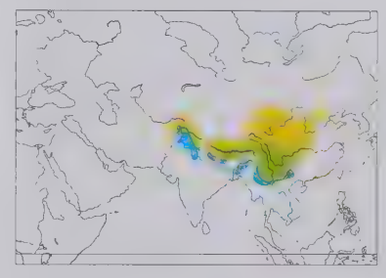
32. **Meadow Pipit**

Anthus pratensis

French: Pipit farlouse **German**: Wiesenpieper **Spanish**: Bisbita Pratense

Taxonomy. *Alauda pratensis* Linnaeus, 1758, Sweden.
Relationships uncertain; possibly forms a clade with *A. roseatus*, *A. cervinus*, *A. spinoletta*, *A. petrosus* and *A. rubescens*. Validity of race *whistleri* debatable, possibly only a clinal variant. Proposed races *enigmaticus* (described from Tashkent) and *theresae* (W Ireland) included, respectively, in nominate and *whistleri*. Two subspecies tentatively recognized.
Subspecies and Distribution.
A. p. pratensis (Linnaeus, 1758) - breeds SE Greenland, Iceland, and from N, NW & C Europe (except N Scotland and Ireland) E to W Siberia, S to S France and C Romania; has bred Italy (Appennines); isolated population in Caucasus (border mountains of Georgia and Armenia). Winters S to N Africa, Middle East and SW Asia.
A. p. whistleri Clancey, 1942 - N Scotland and Ireland.



Descriptive notes. 14·5-15 cm; unsexed 14·5-22 g, male mean 18·6 g, female mean 19·5 g. Small streaked pipit with rounded wings and slender bill. Has pale eyering, brown or yellowish-brown ear-coverts, narrow blackish malar stripe; above, earth-brown or greenish olive-brown, with broad brownish-black streaks on top of head, mantle, scapulars and back; wings darker, remiges with narrow greenish or olive edgings, tertials and upperwing-coverts blackish-brown with pale olive or whitish edgings (two wingbars); tail dark brown, central feather pair fringed greenish-olive, T5 with distal white wedge on inner web and white tip of outer web, outermost pair with whitish outer web and large white distal patch on inner web; whitish to greyish or yellowish-buff below (varies according to degree of plumage wear, palest when worn), throat side, breast and flanks broadly streaked blackish-brown; underwing-coverts and axillaries buffy white; iris blackish-brown; bill dark brown, pale brownish-flesh base of lower mandible; legs pale yellowish-brown to flesh-brown, hind claw long. Sexes alike. Juvenile is more buff-brown above with more obvious streaking, more buff or off-white below, flanks virtually unstreaked. Race *whistleri* is more strongly marked than nominate, with heavier streaks on back, has deeper rufescent olive-brown upperparts. Voice. Aerial song a series of several segments, each comprising a number of uniform notes such as "tsip", "tchip", "tyie", "zu", "tu", "tselp", "tlip" and similar, starts quietly and becomes louder and faster, rising in pitch, usually ending with a flourish as "tee-swia-swia"; song from ground simpler, a repetition of "tsip" or "zi" notes. Call a thin, high-pitched squeak, e.g. "psiip", "pheet" or "isst", often repeated 1-3 or more times; louder version when alarmed; also "chutt" or "chitt" as contact call, "sitt-it" when nervous.
Habitat. Breeds in wide variety of open habitats, such as tundra, moorland and heathland, bogs, saltmarshes, dunes, coastal meadows, hillsides, forest clearings, fallow land, occasionally arable land; peatland a preferred habitat in N Europe; mosaic of heather (*Calluna*), bog and grassland probably the optimum habitat in British uplands. Similar habitats in winter, when also found along seashores. Breeds from sea-level to c. 3000 m, in S of range mainly 800-1600 m.
Food and Feeding. Small invertebrates less than 5 mm long; also seeds. Wide range of invertebrates recorded, including, among others, springtails (Collembola), mayflies (Ephemeroptera), dragonflies (Odonata), stoneflies (Plecoptera), grasshoppers (Orthoptera), earwigs (Dermaptera), bugs (Hemiptera), beetles (Coleoptera), alderflies (Neuroptera), scorpion flies (Mecoptera), larval and adult moths (Lepidoptera), flies (Diptera), ants (Hymenoptera), spiders (Araneae), ticks (Acarina), centipedes (Chilopoda), woodlice (Isopoda), amphipods, snails (Mollusca), and lumbricid and polychaete worms (Annelida). In Germany, Norway and Britain, flies and beetles were the dominant items in stomachs, with hymenopteran larva and ants also important in all studies; spiders and harvestmen (Opiliones), moth caterpillars and bugs also significant. In England, adult dipterans formed 70% of food items, a further 19% being insect larvae. In another English study, first-brood chicks fed mainly with craneflies (Tipulidae) (85% by number), as well as mayflies (11%), other adult flies (3%) and their larvae (0·5%), and stoneflies (0·5%); for second broods, later in the season, the number of craneflies dropped to 41%, whereas mayflies increased to 30% and adult flies and moths formed, respectively, 11·5% and 7·4% of nestling diet. Various plant seeds also taken; seeds of grasses (Gramineae), sedges (Cyperaceae) rushes (Juncaceae), heaths (Ericaceae) and crowberries (*Empetrum*) important in autumn and winter. Will also take bread and suet crumbs on occasion. Forages on ground in short vegetation, usually less than 10 cm tall. Walks or runs; picks prey items from ground and vegetation; occasionally reaches up for a flying insect, but rarely pursues aerial insects in flight. Observed to wade in shallow water. Often in small to large flocks on passage and in non-breeding season.
Breeding. Season late Mar-Aug, later at high altitudes; double-brooded in C & W Europe (rarely in N), occasionally three broods. Monogamous; territorial. In song flight, male rises to c. 20 m, then descends with wings half-spread, tail slightly raised. Nest a neat cup of grass, lined with finer grass and hair, concealed in vegetation on ground. Clutch 2-7 eggs, clutch size larger with increasing latitude, mean in W Germany 4·64, in Norway 5·42 in S and 5·75 in N (Finnmark); incubation 13 days, by female alone, occasionally assisted by male; chicks fed by both parents for c. 12·5 days, may leave nest before able to fly; post-fledging care by both parents, for c. 12-14 days.
Movements. In W Europe mainly resident or partial migrant; many undertake local altitudinal movements, descending from hills to lowlands for winter. Populations from Greenland and Iceland migrate to W Europe. N & E populations are medium-distance migrants, although some make only short-distance hard-weather movements; majority migrate to W, C & S Europe, but some winter farther S, in coastal regions of N Africa and in Middle East (S mainly to NW Arabia), and a few reach desert oases and SW Mauritania; W Siberian breeders migrate mostly to SW Asia, from Iraq and Iran E to Uzbekistan. Autumn migration predominantly in Sept-Nov; departure from wintering areas late Feb, main passage N through Europe in Mar-Apr. Vagrants recorded N to Spitsbergen, W to Madeira and Azores, and E to E Kazakhstan, N Pakistan and Oman; also as far from normal range as Japan.
Status and Conservation. Not globally threatened. Generally common to locally very common, especially in N of range; uncommon in some areas. European population c. 12 million breeding pairs, of which c. 90% in Russia, Norway, Finland, Iceland, Britain and Ireland. Densities highest in N, e.g. 80 pairs/km² in Lappland peatlands, compared with 5-20 pairs/km² in S; only 0·1 pair/10 ha on arable land. Population levels fluctuate according to severity of weather in winter quarters and on spring migration; no long-term trends evident. Some range expansions recorded in France, Finland and Czech Republic, but these offset by declines in the Low Countries, Denmark and C Europe; intensification of agriculture believed to be primary reason for the declines. Forest degradation caused by acid rain has created new breeding habitat in some areas.

33. **Rosy Pipit**

Anthus roseatus

French: Pipit rosé **German**: Rosenpieper **Spanish**: Bisbita Rosado
Other common names: Roseate/Rose-breasted/Vinaceous-breasted Pipit

Taxonomy. *Anthus roseatus* Blyth, 1847, Nepal.
Originally named as *A. pelopus*, but that name invalid. Relationships uncertain; possibly forms a clade with *A. pratensis*, *A. cervinus*, *A. spinoletta*, *A. petrosus* and *A. rubescens*. Monotypic.
Distribution. Breeds in mountains from extreme W China (W Xinjiang) S to NE Afghanistan and E in Himalayas to NE India (Arunachal Pradesh), and in S & E China (C Gansu E probably to Nei Mongol and W Hebei, S to S & E Xizang, Yunnan, W Guizhou and W Hubei); probably also in extreme N & NE Myanmar. Winters S to N India (S to Rajasthan and Assam), Bangladesh and N Thailand.

Descriptive notes. 15-16·5 cm; 17-25 g. Distinctive pipit with seasonal differences in plumage. Breeding plumage distinctive: very long, broad buffish-white to pinkish supercilium, dark grey-brown lores and moustachial stripe; crown and upperparts grey-brown, tinged greenish, crown lightly streaked dark, mantle broadly and distinctly streaked dark grey-brown; wing feathers brownish-grey, edged yellowish-green, median and greater wing-coverts tipped pale grey-brown (two wingbars), tertial edges pale grey-buff; tail brownish-black, central four feather pairs edged yellowish-green, next pair with brownish-white tip, outermost with outer web whitish with brownish-grey tinge; throat pale pinkish; breast to upper belly pink, sometimes tinged buffish, breast side rich buff, rest of underparts pale buffish to whitish, breast side (and occasionally centre) and flanks streaked blackish-brown; axillaries lemon-yellow, underwing-coverts grey, fringed greenish-yellow; iris dark brown; bill blackish; legs pale greyish pink. Distinguished from *A. spinoletta* by more prominent supercilium, heavily streaked mantle and flanks, pale legs. In non-breeding plumage, crown more streaked, has dark malar stripe and patch, more prominent wingbars; pale buffish or whitish below (lacking pink tones), heavy blackish-brown streaking on breast and flanks; base of lower mandible greyish-yellow. Sexes alike. Juvenile resembles non-breeding adult, but browner above, supercilium duskier and less distinct, sometimes indistinctly streaked on back and rump. Voice. Aerial song consists of two parts, twittering during ascent into air, followed by long series of pleasant "tsuli tsuli tsuli" notes during descent; more musical and more varied than that of *A. spinoletta*; also twittering song from ground. Call on take-off a thin single or double "tseep", occasionally triple-noted as "tsip tsip tsip", similar to call of *A. pratensis*, less shrill than that of *A. spinoletta*; alarm at nest a mournful squeak.
Habitat. Breeds on alpine meadows and boulder-strewn grassy slopes, especially near patches of melting snow and on marshy or waterlogged ground; mostly to 4200 m, but to 5300 m in Nepal. Winters in foothills and on plains on short grassland, often near water, and in marshy areas and paddyfields, down to 1500 m.
Food and Feeding. Insects, seeds and berries. Forages on the ground; picks food items from ground surface or from low vegetation. Ingests grit.
Breeding. Breeds end May to Aug, rarely Sept; occasionally double-brooded. In display-flight, male rises into air and sings, descends slowly on outstretched wings. Nest a cup of grass, lined with finer grass and some hair, built in depression, apparently made by the bird itself, under rock or tuft of grass. Clutch 3-4 eggs, usually 4; incubation and fledging periods not documented. Nest sometimes parasitized by cuckoos, e.g. Himalayan Cuckoo (*Cuculus saturatus*).
Movements. Post-breeding movement to lower elevations; N populations migratory. Non-breeding visitor to foothills of Himalayas in N parts of Pakistan, India (S to Rajasthan and Assam), S Nepal, Bhutan and Bangladesh; in E, winters in S parts of breeding range and S to plains of Myanmar (except W & S), NW Thailand and NW Tonkin. Autumn passage reported Sept-Nov; return N from Mar, but many do not reach breeding grounds until late May. Vagrant on Hainan I (SE China).
Status and Conservation. Not globally threatened. Common breeding bird in mountains of W China and in Himalayas; fairly common to common in C China. Uncommon non-breeding visitor in Myanmar and Thailand.
Bibliography. 34. Red-throated Pipit

Anthus cervinus

French: Pipit à gorge rousse **German**: Rotkehlpieper **Spanish**: Bisbita Gorgirrojo

Taxonomy. *Motacilla cervina* Pallas, 1811, Kolyma, Siberia, north Russia.
Possibly forms a clade with *A. pratensis*, *A. roseatus*, *A. spinoletta*, *A. petrosus* and *A. rubescens*. Birds from W part of Eurasian range (E to Taymyr Peninsula), on average slightly larger and with more contrast in plumage, sometimes recognized as race *rufogularis*; variation, however, apparently clinal. Monotypic.
Distribution. Breeds in N Holarctic, mostly N of Arctic Circle, in narrow band from N Fennoscandia E to NE Russia (Chukotsk Peninsula, S to Kamchatka) and extreme NW USA (W Alaska). Winters predominantly in Africa (mostly S of Sahara) and SE Asia.

Descriptive notes. 14-15 cm; 16·4-29·3 g. Distinctive pipit with seasonal differences in plumage. Male in breeding plumage has deep buffish-pink supercilium, buffish-brown lores and ear-coverts; pale brown upperparts with broad blackish-brown streaking, paler margins of mantle feathers usually forming double "V" or "braces"; primaries and secondaries blackish-brown with narrow buff edgings, tertials and greater and median wing-coverts dark brown with buffish-white tips and edges, lesser coverts dark brown with paler brown edges; tail blackish-brown, central feather pair with buff fringes, T5 with white tip on inner web, T6 with outer web and much of inner web whitish; chin to upper breast deep buffish-pink, upper breast sparsely and narrowly streaked blackish, sometimes more heavily so; rest of underparts buffish-white, lower breast and flanks with bold blackish streaking; underwing-coverts and axillaries greyish-white; iris dark brown; bill dark brown to blackish, base of lower mandible yellowish-flesh; legs yellowish-pink to brownish-flesh. Non-breeding male differs in having supercilium and chin to chest buffish, sometimes tinged pink, whole breast heavily streaked, and blackish malar stripe. Breeding female differs from breeding male in having pink on breast and head less intensive and less extensive, upper breast usually buff and more heavily streaked; non-breeding female resembles male, but lacks pink tinge on supercilium and throat. Immature has buff-white underparts and supercilium, bold black malar stripe, bold black streaking on underparts. Voice. Song, usually in flight, a short series of variable notes followed by several phrases of very thin rattling and buzzing notes, e.g. "chu-chu-chu, swee-swee-swee-swee, psiu psiiu psiiiu siirrrr wi-wi-wi-wi, tswee-tswee-tswee-tswee", some phrases sometimes repeated; simpler version from perch. Calls, often in flight or when flushed, occasionally from ground, include short "tew" and longer, very high-pitched, thin, piercing and slightly descending "teeze", "tseeeaz", "seeeu" or "pseeeeeu", sometimes doubled as "see-seeu" or "teeu teeu".
Habitat. Breeds in willow (*Salix*) mires with many small creeks, sedge (*Carex*) marshes and peat mounds, in tundra. Winters on damp or wet short grassland, often where cattle have trampled muddy bare areas, also on marshes, and at muddy edges of rivers and other wetlands, including paddyfields and coastal flats; in E Africa commonly to 2500 m, occasionally above 3000 m. Often occurs alongside *Motacilla flava* in non-breeding areas.
Food and Feeding. Prey mainly insects, also other invertebrates, and some vegetable matter. Recorded items include mayflies (Ephemeroptera), dragonflies and damselflies (Odonata), grasshoppers and crickets (Orthoptera), cicadas (Cicadidae), alderflies (Neuroptera), larval and adult moths and butterflies (Lepidoptera), ants (Hymenoptera), caddis flies (Trichoptera), flies (Diptera) and beetles (Coleoptera), as well as spiders (Araneae), harvestmen (Opiliones), centipedes (Chilopoda), molluscs, worms (Annelida) and grass seeds (Gramineae). Stomachs from NE Russia (Chukotsk Peninsula) contained mostly ants and sawfly larvae (39·7% of prey items), lepidopteran larvae (26·4%) and beetles (15·7%). In a study in the Yamal Peninsula staphylinid beetles formed 20·5% of items, spiders 15·9% and lepidopteran larvae 12·3%, and scale insects (Coccoidea) were also numerically important; in another Yamal study, 45·4% of items were flies (28·1% chironomids, 10·2% muscids, 7·1% tipulids), with adult lepidopterans and spiders also important. Nestlings at Karigasniemi (NW Finland) were fed mainly with dipterans, hymenopterans (mostly larvae), caterpillars and spiders; diet similar to that of adults. Forages on the ground, often in muddy areas, and among seaweed on seashore; adopts horizontal posture, and walks quickly and wags tail often. Usually in small, loose flocks outside breeding season.
Breeding. Laying early Jun to mid-Jun or Jul in N of range; from end May in S. In song flight, male rises obliquely to c. 20 m, makes parachuting descent; also flutters on horizontal course for up to c. 50 m, before dropping to ground. Nest built by female, initial hollow made by male, both sexes bring material but only male does so in later stages; nest a cup of grass leaves and stems, some moss and dead leaves at base, lined with finer grass, hair and feathers, sited on ground on hummock or bank, sometimes at end of short tunnel. Clutch 2-7 eggs, usually 5-6, mean 5·3, 5·5 and 5·9 in Yamal Peninsula, Finland and Norway, respectively; incubation by female, period 11-14 days; nestlings fed by both parents for 11-15 days. Success variable: fledging success 62·9% at a Finnish study site, 91·8% in the Yamal Peninsula; overall success rate 60·6% in far NE Russia (Chukotsk Peninsula).
Movements. Long-distance migrant. European breeders migrate mainly to sub-Saharan Africa, in a broad band from S Mauritania E to Ethiopia and S to Ivory Coast, N Cameroon, NE DRCongo, N Tanzania; some winter farther N, in Nile Valley and on coasts of N Africa and Red Sea. E populations migrate mainly to SE Asia, SE China and Taiwan, in smaller numbers also to N Indian Subcontinent; rare visitor in N Indonesia and Philippines. Leaves breeding grounds from mid-Aug, passage S through C Europe Sept-Oct, through Middle East mainly Oct-Nov, arrival in Kenya from late Oct; return migration in Kenya and Middle East mainly Mar-Apr, in C Europe during first half May, reaching breeding areas from late May. Timing of migration of E populations similar. Recorded as vagrant in Australia. In North America, migrants regular in autumn along coasts of SW USA (California); vagrant in W Mexico.
Status and Conservation. Not globally threatened. Common to very common; one of the most numerous bird species in arctic tundra. Recent population estimates are 500-20,000 breeding pairs in Norway, 3000 pairs in Finland, 100-1000 pairs in Sweden and 10,000-100,000 pairs in European Russia; global population estimated at 500,000-5,000,000. Little evidence for any changes in status except in Finland, where distribution contracted markedly between 1974-78 and 1986-89 and where the species disappeared from Finnish Lappland; reasons for this unclear.

35. Olive-backed Pipit

Anthus hodgsoni

French: Pipit à dos olive **German**: Waldpieper **Spanish**: Bisbita de Hodgson
Other common names: Olive/Oriental Tree Pipit, Spotted Pipit; Hodgson's (Tree) Pipit, Indian Tree Pipit (*hodgsoni*); Siberian Tree Pipit (*yunnanensis*)

Taxonomy. *Anthus trivialis hodgsoni* Richmond, 1907, Bengal, India.
Appears to be very closely related to *A. trivialis*. Races intergrade in N Japan. Proposed race *inopinatus* (Sakhalin) indistinguishable from *yunnanensis*; *berezowskii*, described from Gansu (C China), inseparable from nominate. Two subspecies recognized.
Subspecies and Distribution.
A. h. yunnanensis Uchida & Kuroda, 1916 - breeds from NW Russia (from W of middle R Pechora, SW Siberia and NE Altai) E to Kamchatka, Sakhalin and Kuril Is, S to N Mongolia, NE China (S at least to Liaoning) and N Japan (Hokkaido); winters in S & SE Asia.
A. h. hodgsoni Richmond, 1907 - breeds from Himalayas (E from NW India) E to C China (S Xizang, and from NE Qinghai, S Nei Mongol and Shanxi S to Yunnan and Sichuan), also N Korea and Japan (S to C Honshu); winters in S & SE Asia.

Descriptive notes. 15-17 cm; 17-26·3 g. Nominate race has broad buffish-white to creamy supercilium bordered black above, rear ear-coverts with white spot above a black spot; black malar stripe; upperparts greenish-olive, with prominent black streaks on forehead and crown, and black streaks on mantle; lesser wing-coverts greenish-olive, other wing feathers blackish, edged greenish or yellowish, greater and median coverts with pale tips forming double wingbar (upper one more prominent); tail dull blackish, edged green, T5 with white distal wedge on inner web, cream-buff tip and inner web, T6 white with proximal grey wedge on inner web; chin to upper breast yellow-buff to whitish, lower flanks olive, rest of underparts white to buffy white, breast and upper flanks broadly and heavily streaked or spotted black, lower flanks somewhat less strongly streaked; axillaries and underwing-coverts yellow to buff; iris ochre-brown or dark brown; bill dark horn-brown, base of lower mandible flesh-coloured to reddish-flesh; legs flesh-coloured or pink, sometimes yellowish. Distinguished from *A. trivialis* mainly by having stronger supercilium, narrower mantle streaks, bolder and broader streaks below, different ear-covert pattern. Sexes alike. Immature is browner above than adult, with streaks below longer, wider, but less well defined. Race *yunnanensis* differs from nominate in much less prominent streaks on mantle (often appears plain), somewhat narrower streaks below. Voice. Song, from treetop or in flight, a repetition of single trilled phrases and short dry rattles at fast pace; calls include loud "teaze", hoarse but thin "teez" or "tseep" in flight, and high, thin, almost inaudible "tsi" or "sit" at rest. Most vocalizations very like those of *A. trivialis*.
Habitat. Breeds on edge of taiga, on grassy and bracken-covered slopes, rocky ground and glades in open forest of oak (*Quercus*), birch (*Betula*), alder (*Alnus*), fir (*Abies*) or pine (*Pinus*); also in secondary growth and wooded or abandoned cultivation and scrub with isolated trees, and on barren lava areas, around marshes and shady areas in paddyfields. Also frequents dwarf juniper (*Juniperus*) or other scrub above timber-line, breeding at up to 4000 m in Himalayas. In non-breeding season occurs in Himalayan foothills, to 2500 m; elsewhere, winters in mango groves and other suitable wooded habitats, including coffee and cardamum plantations, on hills and on plains.
Food and Feeding. Insects, including adult and larval moths and butterflies (Lepidoptera), flies (Diptera), beetles (Coleoptera) and bugs (Hemiptera); also grass (Gramineae) and weed seeds. In one study, weevils (of genera *Tanymecus* and *Myllocerus*) formed a large proportion of stomach contents. Forages on ground, usually close to cover; when disturbed, generally flies in to trees, where it often walks along branches. On wintering grounds in Philippines, recorded as feeding frequently in pines, by walking along branches and probing for insects. In small flocks in non-breeding season.
Breeding. Season Jun-Aug in W Siberia (race *yunnanensis*); May to end Jul/Aug in S of range (nominate); normally double-brooded. In song flight, male rises obliquely from tree perch to c. 15-30 m, makes parachuting descent either directly or in arcs. Nest a cup of moss and dry grass, lined with finer grass and a few hairs, placed on ground under tuft of grass or rock, or in shallow depression. Clutch 1-6 eggs, mostly 3-5, usually 4; incubation, probably by female alone, 12-13 days; young fed by both parents, leave nest at 11-12 days, cared for by parents for a further few days.
Movements. N populations migrate to S parts of Asia, wintering from India E to SE China and S to N Malay Peninsula, N Borneo and Philippines; birds leave breeding areas from late Aug, with arrival in non-breeding quarters from Sept to mid-Oct; most return to breeding areas mid-May to early Jun. S populations also move farther S. Annual vagrant in NW Europe (e.g. Faeroes, Norway, Finland, Germany, Poland, British Is) and in Middle East, less frequently in Mediterranean region (Balearic Is, Malta, Cyprus). Casual migrant in W USA on St Lawrence I and Pribilofs, rare on W Aleutians.
Status and Conservation. Not globally threatened. Common to locally common. European population (NW Russia) estimated to be 35,000-40,000 breeding pairs. In N of range, highest recorded densities in N taiga zone, where typically 2-4 breeding pairs/km² in primary forest habitats. No comparable data available for rest of range, but a common breeding visitor in Himalayas. No evidence for any major change in status.

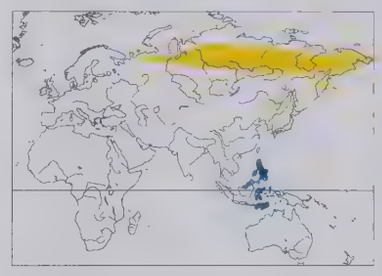
36. **Tree Pipit**

Anthus trivialis

French: Pipit des arbres **German**: Baumpieper **Spanish**: Bisbita Arbóreo
Other common names: Brown Tree Pipit, Eurasian Tree Pipit

Taxonomy. *Alauda trivialis* Linnaeus, 1758, Sweden.
Appears to be very closely related to *A. hodgsoni*. E populations, slightly larger in size and paler in colour, with larger chest streaks and less pointed wing than nominate, sometimes treated as race *sibiricus*, but variation evidently clinal; similarly, proposed races *salomonseni* (from Scotland) and *differens* (NE Turkey) included in nominate; described race *burzil* (Kashmir) considered indistinguishable from *haringtoni*. Three subspecies recognized.
Subspecies and Distribution.
A. t. trivialis (Linnaeus, 1758) - breeds from N & W Europe (except Iceland and Ireland) E to L Baikal and middle R Aldan (possibly to upper R Kolyma) and, in S, from N Mediterranean and N Turkey E to Transcaucasus and N Iran; winters in sub-Saharan Africa and in India.
A. t. schlueteri Kleinschmidt, 1920 - breeds in mountains from E Kazakhstan and NW China (Tarbagatay and Dzungharskiy Alatau) S to Tien Shan and E Afghanistan; winters in C India.
A. t. haringtoni Witherby, 1917 - breeds NW Himalayas (Kashmir E to Garhwal); winters in Indian Subcontinent.



Descriptive notes. 14-15 cm; 15-39 g. Slim, medium-sized pipit with strongly streaked breast, rather heavy bill. Nominate race has buffish supercilium and lores, brown and buff ear-coverts, and blackish-brown malar stripe; olive-brown above, top of head to mantle and scapulars streaked dark brown, back more lightly streaked, rump unstreaked; primaries and secondaries dark brown with narrow pale buff edges, tertials and greater and median wing-coverts brown, edged whitish, lesser coverts brown, edged buff; tail dark brown, T5 with small white spot on inner web, T6 white on outer web and most of inner web; whitish below, pale buff wash on, particularly, breast and flanks, heavy blackish-brown streaking on breast, narrower and more sparse streaks on flanks; underwing-coverts and axillaries dusky grey with pale buff fringes; iris blackish-brown; bill dark brown, pale flesh-coloured base of lower mandible; legs pale brownish-flesh. Differs from *A. pratensis* mainly in more olive tone above, bolder supercilium, thinner streaks on flanks, heavier bill, shorter hind claw. Sexes alike. Immature is more buff-brown, less olive, above, pale feather edgings often giving slight scaly effect, paler below. Race *schlueteri* differs from nominate in having blunter wing and longer tail, broader dark streaks and paler olive-grey fringes on upperparts, more heavily streaked black underparts, also wider and deeper base of bill; *haringtoni* resembles previous, but slightly paler above, streaks below extend farther down on flanks, differs from nominate race in more earth-brown (less olive) upperparts, paler fulvous breast and flanks, heavier streaking on breast. Voice. Song, from treetop or in flight, up to 8 seconds long, a series of trills and repeated notes, has several contrasting sections, generally ending with far-carrying "seee-er, seee-er, seee-er". Call a single drawn-out "tseep" or "teez" in flight or when alarmed; also high-pitched "seet-seet-seet".
Habitat. Breeding habitats include woodland edge, open woodland, cleared woodland and young conifer plantations, often with isolated remaining tall trees, also heathland or grassland with developing scrub and trees; from sea-level to just above tree-line, to 2300 m in S Europe (Alps); at 2800-4000 m in Himalayas (race *haringtoni*). On passage favours similar habitats, as well as more open areas. In non-breeding season, occurs in cleared areas in forest, in open savanna, and in cultivation and coffee plantations with tall shade trees; occasionally found in montane grassland with scattered bushes in Malawi; to 3000 m in Africa.
Food and Feeding. Food includes a range of invertebrates, mostly insects; also some plant material in winter. Nestlings fed exclusively with invertebrates. In six dietary studies in Eurasia, beetles (Coleoptera), especially weevils (Curculionidae), were the most important prey. In analysis of stomach contents of 60 birds from Russia, curculionids were found in 75%, bugs (Hemiptera) in 42%, leaf beetles (Chrysomelidae) in 37% and caterpillars in 33%; other prey occurring in 10-18% of stomachs were click beetles (Elateridae), grasshoppers (Orthoptera), ground beetles (Carabidae), chafers (Scarabaeidae) and spiders (Araneae); less common items included rove beetles (Staphylinidae) and nocturnal ground beetles, small flies (Diptera), ants (Hymenoptera), snails, plant seeds. Other prey in Palearctic Region include earwigs (Dermaptera), lacewings and snake flies (Neuroptera), caddis flies (Trichoptera), harvestmen (Opiliones) and millipedes (Diplopoda). In African non-breeding quarters, grasshoppers, beetles, lepidopterans, bugs and termites (Isoptera) are important prey; stomachs of birds from Zimbabwe contained, among other items, leaf beetles (Chrysomelidae), weevils and other coleopterans, larval and adult butterflies and moths (Lepidoptera), and heteropteran bugs. Plant material taken in breeding range includes fruits, e.g. of bilberry (*Vaccinium myrtillus*), buds of aspen (*Populus tremulus*), and seeds of pine (*Pinus*) and birch (*Betulus*); millet (*Panicum*) grain as well as nectar of *Erythrina* taken in Africa. Forages mostly on ground, mainly among leaf litter and low herbage, also occasionally on twigs, branches and trunks of trees and on stumps. Often in small to medium-sized flocks on passage and in winter.
Breeding. Season late Apr to Aug in NW Europe, May to end Jul in India; often two broods, rarely three. Monogamous, occasionally polygamous; territorial. In song flight, male makes angled ascent from tree perch to c. 15 m, occasionally to 30 m or more, descends in parachute fashion, alights on same perch or another one. Nest built by female, a substantial cup of dry grass, often with moss foundation, lined with finer grasses, placed in depression in ground. Clutch 2-8 eggs, usually 4-6; incubation by female, period 12-14 days; chicks fed by both parents, fledging period 12-14 days, but chicks often leave nest several days earlier. Success rates of 54-72% reported (74-87% of eggs hatch, from which 73-83% of chicks fledge). Nests parasitized by Common Cuckoo (*Cuculus canorus*).
Movements. Long-distance migrant. W populations of nominate race migrate to Afrotropics, spending non-breeding season in region from W Africa E to Ethiopia and, in E Africa, S to W Angola, NE Botswana and NE South Africa; a few move only as far as Mediterranean region and in Persian Gulf states; E populations move to Indian Subcontinent. Both *schlueteri* and *haringtoni* winter wholly in India. Leaves breeding grounds in Aug-Sept, main passage in W Mediterranean during Sept, in Middle East during mid-Sept to late Oct, peak arrival in S parts of Africa in late Oct and early Nov; departure from wintering areas from Feb/Mar, arrives in C Europe from early Apr, reaching N parts of breeding range in May. E migrants reach Indian Subcontinent in late Aug and early Sept, departing from mid-Mar to early May. Vagrants recorded N to Spitsbergen and E to extreme NW USA (Alaska) and Japan; also on several islands of E Atlantic, including Madeira and Cape Verde Is.
Status and Conservation. Not globally threatened. Common throughout range. European population recently estimated at c. 17,000,000 pairs, excluding c. 10,000,000 pairs in European Russia; over 4,000,000 pairs in Sweden alone. European population has probably remained stable since 1970, with decreases or increases in only a few countries. Marked decline noted in Netherlands since 1900, and declines have occurred also in England, N Finland and Switzerland; by contrast, range expansion recorded in Scotland during 20th century. Expansions and fluctuations due partly to changing nature of habitats; for example, newly planted conifer forest on upland moorland may cause local increases, but, as trees mature, numbers of this pipit decrease, only to increase again when clear-felling and replanting take place; recently coppiced broadleaf woodland can also cause temporary local increases. No apparent threats in wintering areas; in Africa, clearance of forest for agriculture may, if scattered trees retained, provide more suitable habitat than that offered by dense-canopy forest.
Bibliography. 37. **Pechora Pipit**

Anthus gustavi

French: Pipit de la Petchora **German**: Petschorapieper **Spanish**: Bisbita del Pechora
Other common names: Siberian Pipit; Menzbier's Pipit (*menzbieri*)

Taxonomy. *Anthus gustavi* Swinhoe, 1863, Amoy, China.
Relationships unclear; possibly close to *A. hodgsoni* and *A. trivialis*. Race *menzbieri* considered a separate species by some taxonomists. Race *stejnegeri*, of which *commandorensis* a junior synonym, doubtfully separable from nominate. Three subspecies recognized.
Subspecies and Distribution.
A. g. gustavi Swinhoe, 1863 - breeds N Russia from NW of Urals (W of R Pechora) E to Chukotsk Peninsula, S to middle R Yenisey, middle R Lena and Kamchatka; migrates to Philippines, N Borneo and Wallacea.
A. g. stejnegeri Ridgway, 1883 - breeds Commander Is; migrates probably to E Asia.
A. g. menzbieri Shulpin, 1928 - breeds Russian Far East (middle Amur Valley, S Ussuriland) and extreme NE China (E Heilongjiang); wintering area unknown.

Descriptive notes. 14 cm; 19·8-26 g. Distinctive pipit with heavily striped upperparts. Nominate race breeding has long, narrow buffish supercilium, ochre-buff ear-coverts indistinctly streaked and spotted black, thin black malar stripe, large black patch on side of lower throat; forehead and crown black, distinctly streaked buffy, hindneck buff, streaked black; mantle and scapulars black with broad whitish fringes, forming distinctive pale "braces" on mantle with parallel pale bar on outer side running along anterior half; back, rump and uppertail-coverts rufous-buff to yellow-buff, sharply streaked black; wing feathers brownish-black, fringed greyish and olive-brown, greater and median wing-coverts with pale tips forming wingbars (greater-covert bar less distinct); tail blackish, T5 grey with pale distal half of inner web, T6 with outer web greyish or isabelline, distal half of inner web buffy or pale isabelline, proximal half dark grey; mainly buffy below, more creamy or white on centre of belly, prominent black streaks on breast, belly side and flanks; axillaries and underwing-coverts greyish, suffused with buff; iris brown to dark brown; upper mandible dark horn-brown, lower mandible paler; legs pale horn, grey, pinkish or yellowish. Distinguished from most other pipits by more heavily streaked upperparts; from *A. cervinus* (non-breeding plumage) mainly by blacker, broader and more sharply defined streaks above, with more distinct white "braces". In non-breeding plumage has less bright pale streaking above, whiter wingbars, paler underparts. Sexes alike. Immature has less clearly defined streaking below, streaks extending to throat and belly. Race *stejnegeri* is slightly larger and paler than nominate; *menzbieri* has shorter wing, is more extensively black above with narrower and paler feather edgings, deeper yellow-buff below, deeper buff undertail-coverts. Voice. Song, in flight, less often from perch or ground, rather quiet, a rapid trill as that of Wood Warbler (*Phylloscopus sibilatrix*), followed by low throaty warble, or alternated with long buzzing rattles, variable; *menzbieri* a low-pitched, muted buzzing, e.g. "ppdzhzhzhzhzhzhzhzheep-zhzhzheepp" or "cheep-cheecheecheezhzhzhzhzh cheenee" and other variations, sometimes likened to song of Grasshopper Warbler (*Locustella naevia*); *stejnegeri* also variable, e.g. "zi-zi-zi-zi-zeerrrrrrrr-zezezezeze" heard, and likened to song of River Warbler (*Locustella fluviatilis*), but reported also as resembling song of *A. trivialis* or of an *Emberiza* bunting; degree to which races differ vocally uncertain. Call a sharp, hard "pwit" or "pit", lower-pitched and softer than call of *A. pratensis*, usually repeated 2-3 times.
Habitat. Breeds in bushy tundra and taiga swamps with tall dense sedges, reeds, shrubs and even trees, in zone between tundra to N (inhabited by *A. cervinus*) and taiga forest to S (inhabited by *A. hodgsoni*); mainly in lowlands. In winter, found in wet grassy areas and open woodland.

Food and Feeding. Mainly insects, including dragonflies (Odonata), hymenopterans, beetles (Coleoptera), flies (Diptera, especially of families Tipulidae, Culicidae, Chironomidae, Tabanidae, Syrphidae), mayflies (Ephemeroptera), adult and larval moths (Lepidoptera); also other invertebrates, such as spiders (Araneae) and molluscs. In stomachs of five birds from Chukotsk Peninsula, hymenopterans formed 72·1% of items, various larvae 11·5%, beetles 8·2%, flies and molluscs each 3·3%, and craneflies (tipulids) 1·6%. Neck-collar and stomach samples from L Khanka (S Ussuriland) comprised, by number, 32% flies, 24·2% larval and adult lepidopterans, 14·3% spiders, 9·5% molluscs, 7·5% cicadas (Cicadidae), 6·3% grasshoppers (Orthoptera), 4·8% beetles, as well as a few sawflies (Symphyta) and caddis flies (Trichoptera); in 1977, 27·5% of samples contained spiders, 24·1% moths and 27·5% beetles; in 1978, spiders were found in 27·7% of samples, moths in 55·3% and flies in 67·1%. Forages mainly on ground, picking items from vegetation; reported also as foraging in tree branches in late summer. Skulks.

Breeding. Late Jun to Jul in Siberia; probably single-brooded. Apparently monogamous; territorial, although loose colonies have been reported. In song flight, male ascends high, usually to 30-70 m, then flies somewhat erratically in circles or small arcs, with rapid wingbeats, occasionally hovers. Nest a cup of grass and other leaves, lined with finer material, built on ground in low vegetation or in shelter of tuft of grass. Clutch 4-5 eggs, occasionally 6; incubation 12-13 days; nestlings fed by both parents for 12-14 days.

Movements. Migratory; winter range inadequately known. Passage migrants recorded in Japan, Korea, E China, Taiwan; winter records from Philippines, N Borneo, and widespread in Sept-Mar in Wallacea. Leaves N breeding grounds from mid-Sept, returns late May and Jun; S race (*menzbieri*) departs Aug-Oct, returns end Apr to end May. Several records from Japan; rare migrant in Hong Kong, and casual in spring in NW USA (W Alaska). Accidental in at least nine countries in W Europe, including Iceland and Lithuania; most records (c. 70) from Britain.

Status and Conservation. Not globally threatened. Widespread in subarctic tundra; little information on population levels, but reportedly not numerous. Difficult to locate owing to its secretive behaviour. No evidence for any recent contraction of range or population decline.

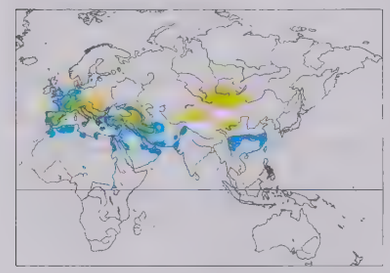
38. **Water Pipit**

Anthus spinoletta

French: Pipit spioncelle **German**: Bergpieper **Spanish**: Bisbita Alpino
Other common names: Mountain Pipit(!)

Taxonomy. *Alauda Spinoletta* Linnaeus, 1758, Italy.



Possibly forms a clade with *A. pratensis*, *A. roseatus*, *A. cervinus*, *A. petrosus* and *A. rubescens*. May form a superspecies, and until recently treated as conspecific, with last two of those. Birds from NW Caucasus sometimes separated as race *caucasicus*, but considered inseparable from *coutellii*. Three subspecies recognized.

Subspecies and Distribution.

A. s. spinoletta (Linnaeus, 1758) - breeds in mountains of C & S Europe; winters W & S Europe and NW Africa.

A. s. coutellii Audouin, 1828 - breeds N, S & E Turkey, Caucasus and mountains of N Iran and Turkmenistan (Kopet Dagh); winters in neighbouring lowlands and S to NE Africa and Arabia.

A. s. blakistoni Swinhoe, 1863 - breeds in mountains of S Russia (E to Transbaikalia), Mongolia, E Kazakhstan, Tadjikistan, Kyrgyzstan, and NW & C China (W Xinjiang, Qinghai); migrates to Pakistan, NW India and S China.

Descriptive notes. 15-17 cm; 18·7-23 g. Nominate race in breeding plumage has mid-grey to brownish-grey forehead to nape and ear-coverts, contrasting broad whitish supercilium; upperparts greyish-brown, mantle with faint dark streaks; remiges and upperwing-coverts blackish-brown with warm brown edges, median and greater coverts with paler tips; tail blackish-brown, T5 with small white tip, T6 with whitish outer web and distal part of inner web; throat whitish, dark malar streak usually faint or lacking (variable); lower throat and breast to upper flanks and upper belly pale pinkish-buff, occasionally slight dark streaking on breast, rest of underparts whitish; underwing-coverts and axillaries white; iris and bill blackish-brown; legs dark brown or blackish-brown. In non-breeding plumage, grey of head is replaced by brown or grey-brown with thin darker streaks, supercilium less distinct, has narrow dark malar stripe and patch, warm brown upperparts indistinctly streaked dark (except on rump), whitish underparts streaked dark brown on breast and flanks; base of lower mandible usually paler, yellowish. Sexes similar, female on average more brownish, less grey, on head. Immature resembles non-breeding adult, but browner and with more obvious streaking above, darker streaking below. Race *coutellii* is smaller than nominate, slightly paler and more streaked above, whitish colour on outer tail feather tinged greyish, in summer plumage has pinkish colour of underparts more rufous-tinged and more extensive; *blakistoni* is larger and paler than previous, with less heavy streaking, and whiter areas on outer rectrix. VOICE. Song, from perch or in flight, a rattling and tinkling series of 4-5 segments, each of one type of monosyllabic or disyllabic note, e.g. "dwis", "wiss-wiss", "siib", "zi-zi", " bit", "dwee", full song 9-12 seconds long and has been transcribed as "vitt vitt vitt-vitt-vitt vietviet viet viet... tri tri tri tri tri... tsia tsia tsia tsia" or with final part a rattled repeated "rirrt"; generally intermediate between those of *A. pratensis* and *A. trivialis*, and both louder and more melodious than former's. Call a single or double short, sharp, unmusical "(h)isst", "wisst", "dzip", "tsi", "tsiip", "tsupi" or "chui", more grating than call of *A. pratensis*, often repeated several times when bird flushed; other calls include "psri", "psiet", "psscht"; in non-breeding season also "tslp" or "pheet".

Habitat. Breeds on alpine pastures and high-lying mountain meadows with short grassland and scattered rocks, bushes or trees, usually with some wet areas, often on mountain slopes; also stony scree with thickets in far E of range; at 615-3200 m, mainly 1400-2500 m. In winter found on coastal saltings, lagoons, marshes, grassy edges of lakes and rivers, sewage farms, watercress farms, rice fields and other irrigated cultivation, often in association with *Motacilla flava*; occasionally on arable land; lowlands and to 2000 m.

Food and Feeding. Invertebrates; some plant material. In W Europe prey includes springtails (Collembola), stoneflies (Plecoptera), crickets and grasshoppers (Orthoptera), bugs (Hemiptera), lacewings and snake flies (Neuroptera), scorpion flies (Mecoptera), butterflies, moths and caterpillars (Lepidoptera), caddis flies (Trichoptera), cicadas (Cicadidae), aphids (Homoptera), psocids (Psocoptera), flies (Diptera), sawflies and ants (Hymenoptera), beetles (Coleoptera), spiders (Araneae), harvestmen (Opiliones), centipedes (Chilopoda), millipedes (Diplopoda), snails (Mollusca), *Gammarus* amphipods (Crustacea) and worms (Annelida); algae, berries and seeds also eaten, and in a study on the Poland-Czech Republic border algae formed up to 75% of food by volume in late summer. Neck-collar samples of nestling diet in two study areas, one in Switzerland and the other in C Asia (Tien Shan Mts), showed dipterans and lepidopterans as numerically important in both areas, with psocids also important in Tien Shan Mts. In a neck-collar study in Moravia, three groups of insects were predominant, with dipterans accounting for 36·5% of items, lepidopterans 33·4% and homopteran bugs 21·6%; average length of prey was 8·3 mm; in poor weather, caterpillars and adults and larvae of scatophagid flies became more important. Forages on the ground, picking up insects and other small invertebrates; occasionally jumps up to take flying insects, or flies out from a perch to catch prey. In severe weather in high mountains, feeds around burrow entrances of marmots (*Marmota*). During breeding season, foraging bouts are more frequent and flight distances greater when weather conditions poor. Generally forages singly or in pairs, sometimes in small groups.

Breeding. Lays end Apr to early Jul in Europe; sometimes double-brooded. Mainly monogamous, occasionally polygynous or polyandrous. In song flight, male rises diagonally to 10-30 m, flies in circle or arc, descends in long looping glide. Nest built mainly by female, sometimes helped by male, a cup of grass stems and leaves, some moss incorporated, lined with finer material and some hairs, placed on ground in side of a bank or hollow, usually well concealed by vegetation, sometimes at end of a tunnel. Clutch 4-6 eggs, occasionally up to 8, mean in former USSR 5·33; incubation by female only, period 14-15 days; chicks brooded by female and fed by male for first few days, thereafter fed by both parents, nestling period 14-15 days. In Europe, 39% of nests in one study were preyed on by stoats (*Mustela erminea*) and snakes, and in another study long-tailed weasels (*Mustela frenata*) and deer mice (*Pesomyscus maniculatus*) were responsible for heavy losses of both eggs and nestlings.

Movements. Predominantly a short-distance or altitudinal migrant; regular migration from high mountains down to lowlands in autumn. Nominate race winters mainly in W & S Europe, including Britain, and S to NW Africa (E to NW Libya); marked site-fidelity reported at wintering locations in NW Europe. Race *coutellii* winters in lower-lying parts of Asia Minor and Caucasus region, also migrates S to Middle East, NE Africa, Arabia and W & S Iran; E breeders (*blakistoni*) winter mostly in Pakistan, extreme NW India and S China (S of R Yangtze). Main departure from breeding areas from mid-Sept, slightly earlier in E (*blakistoni*); peak passage through Middle East from late Oct to late Nov; return northwards begins from Feb-Mar, arrival in breeding areas mainly Apr-May.

Status and Conservation. Not globally threatened. Locally common to fairly common. Patchy distribution in Europe due to altitudinal and habitat requirements, resulting in small isolated populations, together estimated as totalling c. 258,000-351,000 pairs; highest densities range from 2·4 pairs/10 ha in Jura Mts (Switzerland) to 3-3·6 pairs/10 ha in the Alps and to 4·5 pairs/10 ha in prime habitats in the Polish Tatras. Since 1960s several relatively low-altitude populations have been discovered where territories overlap with those of *A. pratensis*; despite potential competition, no evidence for any change in distribution or status of present species. No data on numbers elsewhere (races *coutellii* and *blakistoni*), but species appears to be fairly widespread in suitable habitat and not uncommon; race *blakistoni* possibly breeds also in NE Afghanistan, but confirmation needed.

Bibliography. 39. **Rock Pipit**

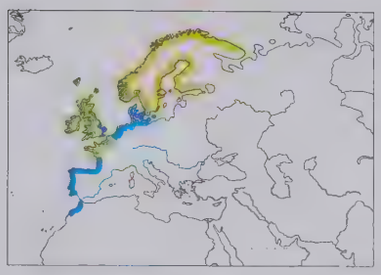
Anthus petrosus

French: Pipit maritime **German**: Strandpieper **Spanish**: Bisbita Costero
Other common names: European Rock Pipit; Scandinavian Rock Pipit (*littoralis*)

Taxonomy. *Alauda petrosa* Montagu, 1798, coast of Wales.

Possibly forms a clade with *A. pratensis*, *A. roseatus*, *A. cervinus*, *A. spinoletta* and *A. rubescens*. May form a superspecies, and until recently treated as conspecific, with last two of those. Variation somewhat clinal, from longer-billed darker birds at NW edge of range to shorter-billed and paler ones in NE; race *kleinschmidti* sometimes merged with nominate. Proposed races *meinertzhageni* (described from South Uist, off W Scotland), *hesperianus* (Arran, off W Scotland) and *ponens* (NW France) considered inseparable from nominate. Three subspecies recognized.



Subspecies and Distribution.

A. p. kleinschmidti Hartert, 1905 - Faeroes and outlying Scottish islands of Shetland, Orkney, Fair Isle and St Kilda.

A. p. petrosus (Montagu, 1798) - coasts of Ireland, Britain (except SE), Channel Is and N & NW France.

A. p. littoralis C. L. Brehm, 1823 - breeds coasts of Fennoscandia and NW Russia; winters W European coasts (S from S Scandinavia) and NW Africa.

Descriptive notes. 16·5-17 cm; 18-32·5 g. Nominate race has narrow, broken whitish eyering, sometimes hint of pale supercilium, grey-brown to olive-brown lores and ear-coverts, pale buff submoustachial stripe, indistinct brown malar stripe; dark olive-grey above, head lightly and thinly

streaked dark, mantle indistinctly streaked dark, rump more olive and plainer; remiges, primary coverts and greater wing-coverts blackish-brown, edged olive-grey, median coverts blackish, tipped olive-grey, lesser coverts dark grey, tipped olive-grey; tail dark brown, T5 with small grey tip, T6 with pale greyish outer web and tip of inner web; chin creamy; underparts light buff to dirty buffish, breast and flanks with heavy but diffuse dark brown streaking (often rather duller below in winter); underwing-coverts and axillaries grey, fringed creamy; iris blackish-brown; bill blackish; legs black to dark brown or dark-reddish-brown. Sexes alike. Immature resembles adult, sometimes browner and more obviously streaked above. Race *kleinschmidti* differs from nominate in having slightly yellower, less olive, tinge above, brighter and yellower ground colour below; *littoralis* has usually more obvious supercilium than nominate, paler wedge on outer rectrix (variable), summer plumage variable, often like nominate, but some are greyer above and have breast pinkish to vinous with streaking reduced or, rarely, almost absent (approaching *A. spinoletta* in appearance). Voice. Song, in flight, a sequence of sharp notes repeated in series, with several theme changes, usually with terminal trill, rather similar to that of *A. pratensis* but louder and with introductory notes slightly lower-pitched; one recording likened to "cheep cheep" followed by 27 double harsh "cheep-a" notes, 16 thin musical "ge" or "gee" notes rising in pitch, 12 higher-pitched "psee", 10 lower-pitched musical notes, and finally three dry rattles, the song lasting 18 seconds. Call a sharp "wiisst", "phi(s)t" or "tsup", lower-pitched and more metallic than that of *A. pratensis* and usually given as single or double call; alarm a high-pitched shrill "chip", "chick" or "ssit".

Habitat. Exposed rocky sea coasts and islands with low vegetation; occasionally breeds away from coast, e.g. up to 400 m inland on St Kilda (W Scotland), or on islands in large inland lakes, e.g. in S Sweden. Sometimes occurs inland along estuaries and at various wetlands, as well as on less rocky coasts, during passage and in winter.

Food and Feeding. Prey comprises a range of invertebrates, from terrestrial snails and slugs (Mollusca), worms (Annelida), small crabs and other crustaceans, and small fish, to aphids (Homoptera), flies (Diptera) and adult and larval beetles (Coleoptera); also seeds. In one study in SW England (Cornwall), periwinkles (*Littorina neritoides*), chironomid larvae, larvae of the kelp fly *Coelopa* and isopods (*Idotea*) were the four common littoral foods taken; amphipod larvae (Talitridae) were sometimes important in late summer. Amphipods important prey in Ireland and Scotland. Wintering concentrations in the Netherlands fed almost exclusively on the mollusc *Asiminea grayana*; winter diet in Norway mostly crustaceans. Forages mainly on the shore, searching among seaweed and on rocks in intertidal area; also on cliff tops in summer. Will wade in sea water, following receding waves to find prey. Also observed to follow a tractor moving pebbles on beach, and to pick up prey exposed by machine's activity. Makes short sallies to take flying insects, but rarely pursues insects far in flight. Usually forages singly or in small loose groups.

Breeding. Mid-Mar to Aug, varying with latitude, from Jun in far N; double-brooded in S of range. Monogamous, but polygyny reported in Sweden (race *littoralis*); territorial. In song flight, male rises to c. 15-30 m, then either flutters forward or in circle for variable distance, or immediately descends in parachute fashion to rock or ground. Nest, built by female, a bulky cup of grass stems, leaves and seaweed, rather flimsily lined with finer material, placed in crevice in cliff, or in small cavity on bank or grassy slope, or under rock or clump of vegetation. Clutch 4-6 eggs; incubation usually by female alone, occasionally assisted by male, period 14-15 days; chicks fed by both parents, fledging period 16 days; fledglings attended by both adults for several days. Average productivity in Britain 2·5 young per pair; in NW France, juvenile mortality more than 68%, and majority of chicks did not survive for more than 4 weeks after fledgling.

Movements. Resident and migratory. Nominate race largely resident, with some short-distance dispersal; *kleinschmidti* may move short distances inland to rivers and lakes or to sandy shores. Most populations of *littoralis* migratory, winter on coasts from S Norway and SW Sweden S to SW Europe, a few reaching NW Africa (Morocco); departure from breeding grounds Sept-Oct, return from Mar onwards, arrival in extreme N not until May. Stragglers recorded in Spitsbergen, Iceland, Canary Is, Mediterranean islands, and several countries in interior of C Europe.

Status and Conservation. Not globally threatened. Common. Global population estimated at c. 408,000 pairs, of which majority (c. 300,000) in Norway. Densities vary from 0·9 to 6 pairs/km of coast; c. 5 pairs/km of favoured coastal habitat in Cornwall (SW England) and 5-6 pairs/km in Loch Sunart (W Scotland). British population has slightly declined since mid-1970s; apparently stable elsewhere. Expansion of range to N in Finland between 1970 and 1990, but this stopped at Quark, probably because of lack of seaweed in Gulf of Bothnia. Few threats to habitat; locally, oil pollution on rocky shores can have adverse effect on this species' invertebrate prey, but generally only temporarily.

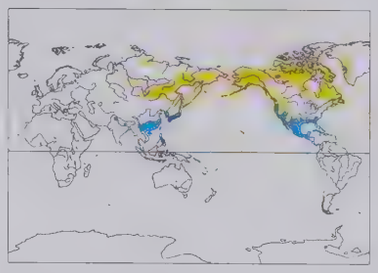
40. Buff-bellied Pipit

Anthus rubescens

French: Pipit d'Amérique **German**: Pazifikpieper **Spanish**: Bisbita Norteamericano
Other common names: American (Water/Rock) Pipit; Siberian (Water) Pipit (*japonicus*)

Taxonomy. *Alauda Rubescens* Tunstall, 1771, Pennsylvania, USA.

Possibly forms a clade with *A. pratensis*, *A. roseatus*, *A. cervinus*, *A. spinoletta* and *A. petrosus*. May form a superspecies, and until recently treated as conspecific, with last two of those. Recent DNA studies, as well as plumage differences, suggest that races may represent more than one species. On the other hand, *pacificus* is doubtfully distinct from nominate in terms of morphology, and merged with latter by some authors. Geographical border between nominate race and *japonicus* uncertain, and population breeding in extreme NE Siberia possibly belongs with former; further study needed. Proposed race *geophilus* (from Aleutians) synonymized with nominate; *haermsi*, described on basis of specimen from non-breeding area in C Asia (E Uzbekistan), considered better treated as synonym of *japonicus*. Four subspecies recognized.



Subspecies and Distribution.

A. r. japonicus Temminck & Schlegel, 1847 - breeds N, C & E Russia in SE Taymyr, W Siberian Plateau, and from E of R Lena, Yakutsk region and L Baikal E to Chukotsk Peninsula, Commander Is, Sakhalin and Kuril Is; winters in S Asia.

A. r. pacificus Todd, 1935 - breeds W North America (Alaska, and Coast Range S to Oregon); winters S to W Mexico.

A. r. alticola Todd, 1935 - breeds C & S Rocky Mts (S from S British Columbia), also locally in mountains W to California (SW USA); winters S to Mexico.

A. r. rubescens (Tunstall, 1771) - breeds N & E Canada, W Greenland and extreme NE USA; winters S to Central America.

Descriptive notes. 14-17 cm; c. 21 g. Nominate race in breeding plumage has broad whitish supercilium tinged pinkish-buff, buffish submoustachial stripe, variable dark malar stripe and patch; grey above, slight dark streaking; wing feathers blackish, pale tips of wing-coverts forming two wingbars; tail blackish-brown, T5 with long white wedge on inner web, sometimes also white tip and white outer edge, T6 with white outer web and long white wedge on inner web; chin and throat pale buffish to pinkish; underparts orange-buff to deep pinkish-buff, variable amount of grey-brown streaking on breast and flanks; iris blackish-brown; bill blackish-brown; legs dark brown to blackish. Distinguished from *A. spinoletta* mainly by slightly smaller size, shorter bill, colour on underparts darker, more orange, and more extensive. In non-breeding plumage is grey-brown above, with dark streaking on back and scapulars somewhat heavier, wingbars more obvious, underparts whitish to rich brownish-buff, usually with more distinct dark streaking; legs sometimes pink-tinged. Sexes alike. Juvenile resembles non-breeding adult, but more distinctly streaked above, paler below, flanks less clearly streaked. Race *pacificus* is very similar to nominate, in breeding plumage underparts slightly yellower, less pinkish-buff, and with more distinct streaking, in non-breeding plumage slightly paler below and spotted rather than streaked, but much individual variation; *alticola* in breeding plumage has underparts darker orange-buff or more rufous-tinged and with sparse streaking, malar patch indistinct or lacking; *japonicus* differs from others in having pale, pinkish legs, in breeding plumage is more light rufous-cinnamon to pink-cinnamon below, distinct spots on cheeks, breast and flanks, in non-breeding plumage is darker greyish-olive above with more pronounced black feather centres on mantle and scapulars, more prominent (whitish) wingbars, usually more heavily marked below, where streaks and spots blacker, more sharply defined and more extensive. Voice. Song, in flight or from perch, a fast series of high notes repeated in phrases, e.g. "treeu-treeu-treeu", "pleetrr-pleetrr-pleetrr", "chwee-chwee", tsip-tsip-tsiru" and the like, continuing for up to c. 15 seconds. Call a high "sipit" or "sip" in flight; higher "tseep", sometimes rapidly repeated as "si-si-si-si-sif", when flushed; alarm near nest a rising "pwisp".

Habitat. North American races breed on treeless tundra with boulder-strewn fields and rocky areas, on barren coasts (Labrador), also on pastures and agricultural land to higher altitudes on mountain slopes farther S; to at least 2700 m. Winters in open, moist habitats along streams and lake edges, on fields, on saltmarshes and on beaches; on migration also on sandbars and open flats near rivers and lakes, on ploughed fields, mudflats, wet fields and wheat pastures. E Siberian race *japonicus* breeds on rocky alpine and subalpine tundra, to 2400 m; in winter favours moist grassland, marshes, irrigated cultivation, wetland edges.

Food and Feeding. Insects, including grasshoppers, crickets and locusts (Orthoptera), beetles (Coleoptera), bugs (Hemiptera), including plant-lice and aphids (Homoptera), also lepidopteran larvae, and ants (Hymenoptera); also other invertebrates, such as spiders (Araneae) and mites (Acarina), small molluscs and crustaceans; also small seeds and berries. Plant material taken mainly in autumn and winter. Forages on ground, by picking; also wades in shallow pools in search of aquatic invertebrates. Reported as eating dipteran larvae from rotting whale carcasses. Often in flocks outside breeding season.

Breeding. Laying mainly Jun-Jul. In brief song flight, male ascends to c. 20-30 m, glides back down to perch in long arc or loop. Nest built by female, male may bring material, a platform of dead grass with cup of fine grasses, often lined with hair, placed on ground in recess, or under rock or grass clump; new nest sometimes built on top of old one. Clutch 3-7 eggs, usually 4-6; incubation by female, period 14-15 days; chicks brooded only by female, fed by both parents, nestling period 13-16 days. Reported success rate 67% (74% of eggs hatched, and 77% of these produced fledglings); in Asia, nests parasitized by e.g. Common Cuckoo (*Cuculus canorus*), chicks sometimes die from infestation by blowfly (*Calliphora*) larvae.

Movements. Migratory. American races winter on W coast S from extreme SW Canada (S British Columbia) and from S USA S to N Central America; regular visitor in much of Mexico, including Baja California, less so in SE, and irregular to rare in Guatemala, El Salvador, Honduras and Jamaica. Leaves N breeding grounds mainly from late Aug and early Sept, reaching non-breeding quarters late Sept to Nov; returns N from Feb-Mar onwards, arrival in N of breeding range in May. Asian race *japonicus* migrates mainly to Japan, Korea and SE China, less commonly N Indochina, N Myanmar and N parts of Indian Subcontinent; apparently regular visitor also farther W, in Uzbekistan and Middle East (Israel); autumn arrival in Japan (Honshu) and Israel Oct-Nov, main departure Mar-Apr, spring arrival on breeding grounds mainly in May. Nominate race recorded as vagrant in at least five countries in Europe, also in NC & E Pacific Ocean (Hawaii, Clipperton I) and NW Atlantic (Bermuda); *japonicus* accidental in W USA, Europe (Sweden, Italy), NE Africa (Egypt) and several countries in SW Asia.

Status and Conservation. Not globally threatened. Common and widespread throughout most of range. Common to fairly common non-breeding visitor in Mexico; possibly breeds in NW Mexico (San Pedro Martír, in N Baja California). North American population recently estimated at more than 19,000,000 individuals. Has been suggested that global warming may have a negative impact on alpine breeding populations of this species in USA and Canada.

41. Short-tailed Pipit

Anthus brachyurus

French: Pipit à queue courte **German**: Kurzschwanzpieper **Spanish**: Bisbita Colicorto

Taxonomy. *Anthus brachyurus* Sundevall, 1850, upper Umlaas River, near Durban, South Africa.
May form a clade with *A. caffer* and *A. sokokensis*. Racial differences rather unclear, and correct assignation of population from S Tanzania disputed; proposed race *eludens* (WC DRCongo) not reliably separable from *leggei*. Two subspecies recognized.

Subspecies and Distribution.
A. b. leggei Ogilvie-Grant, 1906 - disjunct populations in E DRCongo, SW Uganda, Rwanda, N Burundi and extreme NW Tanzania; SE Gabon and S PRCongo through W & S DRCongo to NE Angola and N & C Zambia; and (probably this race) S Tanzania.
A. b. brachyurus Sundevall, 1850 - SC Mozambique (N of Beira); E South Africa (Mpumalanga and KwaZulu-Natal) and E Lesotho.

Descriptive notes. 11·5-12·5 cm; male 15·5-16·7 g, female 13·5-17·2 g. Small pipit with noticeably short tail; has been likened to female of a small bishop (*Euplectes*) or a large cisticola (*Cisticola*) in the field. Has indistinct pale supercilium, more obvious pale eyering; lores and ear-coverts dark olive; blackish upperparts with dull olive-buff feather edgings, rump dark olive-brown; wings blackish-brown, pale olive-buff edges of tertials and wing-coverts; tail dark brown, T5 tipped pale, T6 greyish-white; below, pale yellowish-buff, breast boldly streaked blackish, some streaking on throat, flanks and belly; underwing-coverts and axillaries pale yellowish-buff; iris brown; upper mandible dark brown, lower mandible flesh-coloured; legs flesh-coloured. Distinguished from *A. caffer* by shorter tail, shorter bill, darker (blackish) upperparts, white throat, more heavily streaked breast, more noticeable eyering. Sexes alike. Immature has whole of upperparts dark brown with narrow warm buff edgings, tertials and wing-coverts with sharply defined warm buffish-brown edges, underparts more broadly streaked. Race *leggei* differs from nominate in having feathers of upperparts less strongly edged with olive-buff, heavier streaking below. Voice. Song, in flight, a high, rapid, rather grating series of phrases, "tuweehweeh-weeh wheeh threeohweeh", or series of nasal notes, "bzip, bzeent, bzeeu", or rolling "tip-pee-reep-pip-rip"; wing-snaps in aerial display. Call soft, nasal "tseep".

Habitat. Short open grassland less than 15 cm in height. Moist, often seasonally inundated grassland preferred, but occurs in Zambia on sparsely vegetated ground on sandy soils, or on recently burnt ground. Sea-level to above 1800 m, mainly 800-1500 m.

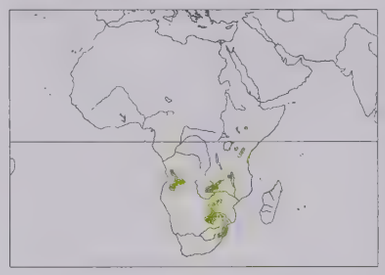
Food and Feeding. Insects and their larvae, also grass seeds (Gramineae). Forages on ground. The most terrestrial of the small pipits, inconspicuous and elusive; flies reluctantly when disturbed, and soon lands in grass and moves away quickly under cover. Generally solitary, occasionally several together in loose aggregation; does not consort with other pipits.

Breeding. Poorly known. Breeds in the rains, in Dec in Angola, Nov-Feb in DRCongo, Nov-Dec in S Tanzania (Iringa highlands) and Sept-Jan in South Africa; one was in breeding condition in Dec in Zambia. Male displays on ground with rapid wing-flicking, or flies in wide circles a few metres above ground while giving nasal calls and buzzing wing-snaps. Nest a small deep cup of coarse grass, lined with finer material, placed on ground between tufts of grass. Clutch 2-3 eggs; no further information.

Movements. Poorly understood. May be resident in some areas, an altitudinal migrant (in KwaZulu-Natal), a local migrant, or an intra-African migrant. Unpredictable locally, although patterns of occurrence seasonal in some areas; in tropics present during or near rains, mainly Sept-Mar at 4°-16° S and mainly May-Aug in C Africa; in South Africa, breeds on lower slopes of Drakensberg escarpment in austral summer, and found in winter along coast and on floodplains (as around L St Lucia). Birds seen near Beira (Mozambique) possibly migrants from E Zimbabwe highlands, but few records from latter area; also recorded on Limpopo floodplain.

Status and Conservation. Not globally threatened. Generally uncommon to frequent throughout most of range, may be more common locally; rare in South Africa, where population estimated at fewer than 3000 individuals. Disjunct distribution, and fragmented populations highly localized. Formerly recorded more widely in South Africa, but has probably disappeared from Gauteng and North-west Provinces, and range in S KwaZulu-Natal may also have descreased; possibly no longer survives in Lesotho; the species' elusive nature, however, makes this difficult to confirm. Habitat is under pressure from commercial afforestation, sugar-cane farming, overgrazing, agricultural intensification, unsympathetic fire regimes, and increasing and dense rural human populations. Opencast coal-mining has caused local losses.

Bibliography. Barnes (2000), Benson (1976), Benson *et al.* (1971), Borrow & Demey (2001), Brooke (1984b), Brown & Britton (1980), Campbell (1989), Chapin (1953), Clancey (1964b, 1969a, 1985b, 1985c, 1990a, 1996), Connor (1980), Davies *et al.* (2003), Dean (1971, 2000), Donnelly (1982), Dowsett (1989), Dowsett & Dowsett-Lemaire (1997), Ginn *et al.* (1989), Harrison *et al.* (1997), Hartman (1985), Keith *et al.* (1992), Lawson, P. (1980), Lawson, W.J. (1965b), Lippens & Wille (1976), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993a), Mendelsohn *et al.* (1988), Milstein (1966, 2000), Newman (1996), Short *et al.* (1990), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Stevenson & Fanshawe (2002), Steyn (1996), Tarboton (2001), Tarboton *et al.* (1987), Vincent (1986), Voelker (1999a, 1999b, 1999c).



42. Bush Pipit

Anthus caffer

French: Pipit cafre **German**: Buschpieper **Spanish**: Bisbita Cafre
Other common names: Bushveld Pipit, Little Tawny Pipit

Taxonomy. *Anthus caffer* Sundevall, 1850, Mohapoani, by Limpopo River, South Africa.
May form a clade with *A. brachyurus* and *A. sokokensis*. Extent of distribution uncertain, and geographical variation and limits of races poorly understood. Birds from Angola included with *mzimbaensis* but smaller and less pale below, almost certainly involve an undescribed race; in addition, birds from extreme SE DRCongo and adjacent Zambia and N Malawi may represent an undescribed race; further study required. Five subspecies recognized.

Subspecies and Distribution.
A. c. australoabyssinicus Benson, 1942 - S Ethiopia (highlands E of Rift Valley).
A. c. blayneyi van Someren, 1919 - S Kenya and N Tanzania.
A. c. mzimbaensis Benson, 1955 - Angola (Cuanza Norte and Bié S to N Huíla, E to N Moxico), NW Malawi, extreme SE DRCongo and Zambia S to NE Botswana and C Zimbabwe.
A. c. caffer Sundevall, 1850 - SE Botswana, SW Zimbabwe, NE South Africa and W Swaziland.
A. c. traylori Clancey, 1964 - lowlands in NE South Africa (E Northern Province, NE KwaZulu-Natal), E Swaziland and extreme S Mozambique (S of R Limpopo).

Descriptive notes. 12·5-13·5 cm; 16-18 g. Small pipit with warm-coloured upperparts. Nominate race has indistinct buffish supercilium, buff-flecked dark brown lores and ear-coverts; warm reddish-brown upperparts are boldly streaked with dark brown, rump and uppertail-coverts only slightly streaked; wings dark brown, tertials and upperwing-coverts broadly edged and tipped warm buff; tail dark brown, outer rectrix white except at base of outer web; pale buff below, breast and flanks streaked dark brown; iris brown; upper mandible dark brown, lower mandible pale horn; legs light brown, hind claw short and curved. Distinguished from closely similar *A. brachyurus* by longer and broader tail, from *A. sokokensis* by darker and less boldly patterned underparts. Sexes alike. Immature is paler than adult, and more spotted above. Race *blayneyi* is more sandy buff than nominate, has rump streaked, belly whiter; *australoabyssinicus* is paler than last, has finer streaking above, streaks below extend to throat; *traylori* is smaller and less reddish above than nominate, rump more olivaceous and with dark brown streaks, underparts whiter; *mzimbaensis* resembles previous in colour but is much larger, but some Angolan birds smaller and less white below (also with less heavy streaking). Voice. Song, from tree perch, a repeated phrase of 2-3 notes, first note lower, "werrp-cheer, werrp-cheer, werrp-chirr" or "zweep-tseer, zweep-tseer, zweep-tseer". Call a sharp, sibilant "tzee-eep", "seeip", "tseeip" or "bzhzhzht", given when landing in a tree, or high nasal "meeh-tjih meeh-tjih" (first note rising); also a very distinctive, long descending "sseeeoo".

Habitat. Tree and bush savanna or open woodland with rather sparse ground cover, often with bare sandy patches or with scattered rocks and stones, from near sea-level to 2200 m. Recorded at edges of, or along, drainage lines in *Brachystegia* woodland, in acacia (*Acacia*) woodland, and in savanna, bushed and wooded grassland, and acacia thickets. In N Tanzania (Serengeti), appears to favour areas where grass cover between bushes reduced by heavy grazing by mammals. In SE Botswana, occurs in open woodland with wattles (*Peltophorum*) and acacias on lower slopes of rocky hills, heavily grazed and trampled by domestic livestock.

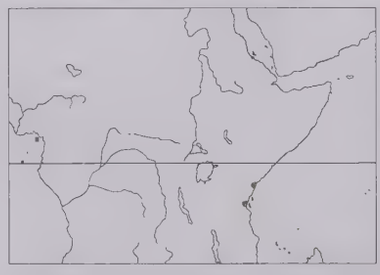
Food and Feeding. Prey consists of small insects and other invertebrates. Forages on the ground among leaves, in grass or on bare patches; when disturbed, flies jerkily up to top of a tree. Usually solitary or in pairs; occasionally in small loose flocks outside breeding season.

Breeding. Poorly known. Laying dates Mar-Apr in Kenya, Nov and Jan in Zimbabwe, and Oct-Mar in South Africa. Nest a small thick-walled grass cup, lined with rootlets, built on ground, concealed under tuft of grass. Clutch 2-3 eggs, mean 2·5 in South Africa, 2·7 in Kenya; no information on incubation and nestling periods.

Movements. Not well understood. Partially nomadic in E Africa (race *blayneyi*), movements coinciding with onset of rain; E populations of *mzimbaensis* undertake post-breeding movement to N Zambia, adjacent DRCongo and Malawi; *traylori* seems to be sedentary. Records in Zambia mainly in May-Sept dry season, suggesting that movements occur; in S Africa, however, present throughout year in all parts of range and reporting rates did not support concept of comprehensive migrations.

Status and Conservation. Not globally threatened. Localized and generally uncommon; not uncommon in Angola; very scarce in Malawi. Apparently disjunct distribution, but perhaps overlooked in some areas; possibly more widespread than currently realized. No evidence for any change in status over recent decades. Heavy grazing by domestic stock in some parts of its range may provide the sparse ground cover that this species prefers.

Bibliography. Aspinwall (1973, 1990), Aspinwall & Tucker (1971), Benson (1946a), Benson & Benson (1977), Britton (1980), Butler (1986), Campbell (1989), Chapin (1953), Clancey (1964b, 1989a, 1990a, 1991, 1996), Dean (1971, 1987, 2000), Ginn *et al.* (1989), Harrison *et al.* (1997), Hunter (1985), Irwin (1981), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1963), Maclean (1993a), Milstein (2000), Parker (1999), Penry (1994), Roberts (1913), Short *et al.* (1990), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Stevenson & Fanshawe (2002), Stjernstedt (2004), Stronach (1990a), Tarboton (2001), Tarboton *et al.* (1987), Voelker (1999c), Wood (1993).



43. Sokoke Pipit

Anthus sokokensis

French: Pipit de Sokoke **German**: Sokokepieper **Spanish**: Bisbita del Sokoke

Taxonomy. *Anthus sokokensis* van Someren, 1921, Sokoke, Kenya.
May form a clade with *A. brachyurus* and *A. caffer*. Monotypic.

Distribution. Coastal forest in E Kenya and NE Tanzania.

Descriptive notes. 12 cm; 12-17 g. Small pipit with richly coloured upperparts, prominent pale wingbars, heavily streaked breast. Has narrow buffish-white supercilium, ear-coverts streaked pale buff and dark brown; broadly streaked warm buff and blackish-brown above, rump and uppertail-coverts tinged rufous; primaries and secondaries blackish-brown with narrow buff edges; tertials and inner greater wing-coverts dark brown, edges pale rufous or creamy buff (forming panel on closed wing); median coverts and outer greater coverts with broad buffish-white tips forming prominent wingbars; lesser coverts dark brown with broad buff fringes; tail feathers pointed, blackish-brown, central pair with broad rufous-buff edges, T5 tipped white, T6 white except for base of inner web; throat white; white with yellowish-buff tinge below, broad blackish streaks on upper breast, fine blackish streaks on lower breast, flanks and belly; underwing-coverts and axillaries white; iris dark brown; upper mandible blackish-horn, lower

mandible pinkish with brown tip; legs fleshy pink. Sexes alike. Immature unknown. Voice. Song, in flight, repeated high-pitched phrases e.g. "eee-see" or "su-eeee-see", middle note highest, each phrase separated by brief pause. Contact call, from tree or ground, high-pitched descending "sweer" or "tseer".

Habitat. Coastal forest. In Kenya (Arabuko-Sokoke Forest), particularly in dense *Afzelia*-dominated stands on white soil and in undisturbed *Brachystegia*-dominated woodland, also in degraded forest, and in *Cynometra-Manilkara* forest and lowland rainforest. In Tanzania (Kiono Forest), found in structurally uniform forest with 66% canopy cover, well-developed shrub layer, and sparsely vegetated ground with thick litter layer with much rotting wood and abundant terrestrial invertebrates; at Vikindu, also observed in a patch of forest with canopy cover 60-90%, very sparse shrub layer and almost no undergrowth.

Food and Feeding. Insects, such as termites (Isoptera) and beetles (Coleoptera). Forages among leaf litter on forest floor. When flushed, usually flies to high perch; sometimes may fly only short distance before dropping down to ground again.

Breeding. Undulating aerial display over forest canopy. No other information.

Movements. Resident.

Status and Conservation. ENDANGERED. Restricted-range species: present in East African Coastal Forests EBA. Global range very small, c. 2270 km². Shy and easily overlooked; often located only by its call. Recorded in seven or eight forests. Main stronghold in Arabuko-Sokoke Forest, in Kenya, where recent studies suggest population of 13,000 individuals, much higher than estimates made in 1970s and 1980s; densities up to 1 pair/2 ha in *Afzelia*-dominated forest, 2·8 birds/ha in undisturbed *Brachystegia* forest (but only 0·9/ha recorded in logged-over forest). Very rare at all known sites in Tanzania, and probably extinct at some. Has suffered greatly from degradation and loss of habitat; many coastal forests have disappeared or become severely degraded through logging, and through encroachment for crop-growing, stock grazing and firewood-gathering. Recent research indicates that continued presence of this pipit probably compatible only with very limited forest exploitation. Although an area of 400 km² of Arabuko-Sokoke has protected status, logging and replanting with exotic species remain legal activities; c. 43 km² fully protected, but legal regulations often ignored, and lack of funds for forest officers an added problem. In Tanzania, the species is the target of conservation efforts at Kiono and Vikindu Forest Reserves, although rare at both.

Bibliography. Bennun & Njoroge (1999), Bennun & Waiyaki (1992), Britton & Zimmerman (1979), Britton *et al.* (1984), Burgess, Cutts & Huxham (1991), Burgess, Huxham *et al.* (1991), Burgess, Mwasumbi *et al.* (1992), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Fanshawe (1991), Fishpool & Evans (2001), Green & Hirons (1991), Keith *et al.* (1992), Kelsey & Langton (1984), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960), Mlingwa (1991, 1993, 1996), Mlingwa *et al.* (1993), Moreau (1940b), Musila *et al.* (2001), Ripley & Bond (1971), Short *et al.* (1990), Stattersfield & Capper (2000), Stevenson & Fanshawe (2002), Turner (1977a), Waiyaki & Bennun (1999), Zimmerman *et al.* (1996).

Genus *TMETOTHYLACUS* Cabanis, 1879

44. Golden Pipit

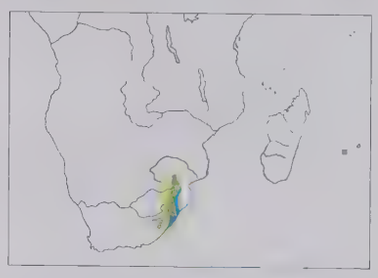
Tmetothylacus tenellus

French: Pipit doré **German**: Goldpieper **Spanish**: Bisbita Dorado

Taxonomy. *Macronix tenellus* Cabanis, 1878, Taita, south-east Kenya.
Apparently closely related to *Hemimacronyx* and *Macronyx*. Monotypic.
Distribution. SE Sudan and NE Uganda, and from NW Somalia and E & SE Ethiopia S to E Kenya and NE & C Tanzania.

Descriptive notes. 14-16 cm; male 18-21·5g, female 18-22 g. Distinctive motacillid with much yellow in wing and on side of tail; no feathering on lower tibia. Male unmistakable: has broad yellow supercilium, dusky-streaked greenish lores and ear-coverts; top and side of head, also mantle and scapulars, streaked blackish-brown and yellowish-green, back and rump yellowish-green with less streaking; primaries yellow, outer five blackish distally, inner four sometimes black-tipped; secondaries yellow; tertials dark brown with yellow base, tipped buff; alula and primary coverts yellowish, tipped black; outer greater and median wing-coverts yellow with dark brown bases of outer webs, inner greater and median coverts dark brown with buff fringes, lesser coverts dark brown, edged yellow; central tail feathers dark brown, next three pairs yellow, tipped and edged dark brown, outer two pairs yellow; below, bright golden-yellow, black breastband; underwing-coverts and axillaries yellow; iris and bill brown; legs pale brown, hind claw long and curved. Female has buff supercilium; above, is buffish-brown with dark brown streaks, rump less streaked; wings dark brown, primaries narrowly edged yellow, wing-coverts fringed buff; tail dark brown, outer rectrix yellowish-buff, adjacent one with yellowish-buff on inner web; buff below, yellower on centre of belly; underwing-coverts, axillaries and broad edges of inner webs of underside of primaries yellow. Immature resembles female, but breast spotted, young male with bases of secondaries yellow. Voice. Song, in flight or from perch, a series of sibilant or flute-like whistles, "dji-dji-dji-dji-dji-dur-dur" or "tsi-tsi-tsi-tsur-tsur-tsi-tsi-tsi-tsi"; also a grating hurried warbling, "tritt-ritthree-diderruh", as bird descends to ground from treetop.
Habitat. Arid light acacia (*Acacia*) bush, and scrubby grassland; sometimes in very open grassland with a few bushes in lowlands. Quite catholic in choice of habitats, being common in all savanna types, in SE Kenya (Tsavo East National Park). Generally below 1000 m, including coastal lowlands; occasionally to 1800 m.
Food and Feeding. Small insects, probably also other invertebrates. Forages in grassland; also takes items from herbage and bare ground. Frequently perches on bushes and trees and wags tail up and down in *Motacilla* fashion. Usually seen singly or in pairs; occasionally in presumed family parties, or in loose flocks outside breeding season.
Breeding. Lays in May in Ethiopia and Somalia; in Kenya, Jul on coast and Nov-Dec and Apr in SE; Nov in C Tanzania; mainly during rains, Dec-Jan, elsewhere. Monogamous; territorial. In song flight, male flutters upwards from treetop or bush, then glides to ground with wings raised in "V" over back. Nest is a cup of stems and grasses, lined with finer material, hidden low in a bush or just above ground in a grass tuft. Clutch 2-4 eggs; incubation and fledging periods not documented.
Movements. Rather poorly understood; probably migrates regularly between N and S of range, as indicated by birds caught at night at buildings in E Kenya, Nov to mid-Jan. Probably only a dry-season visitor in SE Sudan. In Somalia, present in NW mid-May to end Sept but not at other times, although a few birds remain in S, the rest presumed to have moved farther S, into Kenya; in 1961, S-directed passage noted in late Jun in N Somalia. In Kenya and Tanzania numbers fluctuate erratically, but present mainly Nov-Apr (during and after rains); at Mweka (N Tanzania) passes through in large numbers from Apr to Jun but few at other times; in Tsavo East National Park a definite increase occurs at onset of the rains, with peak numbers in Dec, then decrease through to Apr as grasslands dry out, and absent or nearly so in May-Sept. Few records of vagrants in South Africa and Zimbabwe, possibly result of extreme dispersal or occasional long-distance eruptions. Recorded once farther N, in S Arabia (Oman) in Jun.
Status and Conservation. Not globally threatened. Common in both NW & S Somalia, and locally common in Kenya and Tanzania; uncommon in S Sudan. In Tsavo National Park, in Kenya, reasonably high densities in bushed and wooded grassland, and lowest densities in open grassland and in woodland.
Bibliography. Archer & Godman (1937-1961), Ash & Miskell (1998), Backhurst & Pearson (1977), Bennun & Njoroge (1999), Benson (1946a, 1982), Briggs & van Zandbergen (2002), Brooke (1972b), Brooke & Irwin (1972), Brown & Britton (1980), Byaruhanga *et al.* (2001), Cave & Macdonald (1955), Clancey (1960b), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Friedmann (1937), Gallagher (1986), Ginn *et al.* (1989), Harrison *et al.* (1997), Jackson (1905), Keith *et al.* (1992), Lack (1985), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1963), Maclean (1993a), Newman (1996), Patten (1986), Schels & Lavoyer (1987), Short *et al.* (1990), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Stevenson & Fanshawe (2002), Stronach (1967), Turner (1977b), Zimmerman *et al.* (1996).

Genus *HEMIMACRONYX* Roberts, 1922



45. Yellow-breasted Pipit

Hemimacronyx chloris

French: Pipit à gorge jaune **German**: Gelbbrustpieper **Spanish**: Bisbita Pechigualdo

Other common names: Yellow(ish)-bellied Pipit, Yellow-breasted Longclaw

Taxonomy. *Anthus chloris* M. H. K. Lichtenstein, 1842, Eastern Cape, South Africa.
Genus apparently closely related to *Tmetothylacus* and *Macronyx*. Previously placed in genus *Anthus*, a treatment still preferred by some authors. Appears, however, much closer to *H. sharpei*, with which it probably forms a superspecies. Monotypic.
Distribution. Drakensberg in South Africa (Mpumalanga and W KwaZulu-Natal S to NE Eastern Cape and extreme SE Free State) and E & S Lesotho.

Descriptive notes. 16-18 cm; male 24-25·6 g, two females 25·3 g and 25·8 g. Unmistakable. In breeding plumage has narrow yellowish supercilium, with lores and ear-coverts streaked rich brown, whitish area below eye, thin blackish moustachial stripe; top of head and mantle blackish-brown, feathers edged yellowish-olive, giving effect of broad streaking; nape, rump and uppertail-coverts more grey; remiges and upperwing-coverts blackish-brown with narrow yellow, whitish or buff edgings; rectrices blackish-brown, edged buff, T5 tipped white on inner web, T6 almost entirely white; chin to upper belly bright yellow, brownish tinge on flanks, usually finely streaked brown on upper breast; lower belly to undertail-coverts greyish-white; greater underwing-coverts blackish with white tips, lesser underwing-coverts and axillaries yellow; iris dark brown; bill dark horn, yellowish base of lower mandible; legs yellowish-flesh, hind claw long and weak. In non-breeding plumage, lores and ear-coverts more uniform warm buffish-brown, moustachial stripe indistinct, feathers of upperparts edged warm buffish-brown, chin and throat pale buffish-brown, breast warm buffish and finely streaked brown, centre of belly yellow. Sexes alike. Immature is blackish-brown above, streaked creamy buff on head, scalloped on mantle and back, with tertials and upperwing-coverts broadly and sharply edged creamy buff, buff below, breast more dusky and finely streaked brown, belly centre slightly yellow-washed; resembles young *Macronyx capensis*, but has outer tail feathers white rather than white-tipped. Voice. Song, from perch or in flight, a repeated double "see-chick, see-chick", separated by brief pauses, the "see" note sibilant and soft, the "chick" abrupt and harsh. Call a single whistled "tseeu"; alarm a rapid continuous "chick chick chick".
Habitat. In breeding season restricted to areas of flat or undulating submontane grassland at 1400-2400 m; favours lush grassland with tussocks, and commonest in the least heavily grazed sites. In non-breeding period, also at lower elevations on grassland such as pastures and fallow land or in bush savanna.
Food and Feeding. Diet consists of insects, including mantids (Mantodea) and small beetles (Coleoptera). Skulking and furtive, creeping through grass and running across open spaces. Tends to freeze when approached, or to run, keeping behind cover; flushes at last minute and flies away for rather long distance; sometimes less shy. Usually in pairs; small flocks in non-breeding season.
Breeding. Breeds during Nov-Feb (summer rains). Monogamous; territorial, although sometimes several pairs nest close together. In aerial song display, climbs into air with floppy wingbeats, cruises for c. 100 m, then dives vertically into grass. Nest a cup of stalks, grass blades and rootlets, lined with fine rootlets and frequently also hair, built on ground under tussock or in grass clump. Clutch usually 3 eggs, mean of eight clutches 2·9; incubation and fledging periods not documented.
Movements. Resident and partial short-distance migrant. Some descend to lowlands in austral winter (Apr-Sept), a few moving E to Swaziland and coastal regions of KwaZulu-Natal and Eastern Cape; formerly recorded also in Vaal Basin W to North-east Province (W to Potchefstroom). An old record from S Western Cape (Swellendam).
Status and Conservation. VULNERABLE. Restricted-range species: present in South African Grasslands EBA. Localized and generally scarce within range; more common in N than in S. Rare in Lesotho, known only from Sehlabethebe National Park, where c. 60-80 pairs. Global population estimated at 1500-5000 individuals in 1992, but reassessed as between 2500 and 6500 in 2000. Occurs in Natal Drakensberg National Park; significant numbers, c. 30% of total population, occur in proposed grassland biosphere reserve in Wakkerstroom region of S Mpumalanga and adjacent KwaZulu-Natal. Has undergone range contraction and, probably, population decline as a result of habitat degradation and loss. Threats include overly frequent burning of grassland, and overgrazing and trampling by small livestock. There is a need to maintain low-intensity pastoral farming and to encourage appropriate management of grassland on private land; management practices affect nesting success through influencing the cover, height and density of vegetation; nest success highest in grassland with low-intensity grazing and biannual burning, lowest in heavily grazed, annually burnt plots; nest density, however, found to be highest in lightly grazed, annually burnt plots. Afforestation of montane grasslands an additional major threat, especially in N of range; has been estimated that 50% of the species' population could be lost through commercial afforestation on grasslands if no conservation action is taken.

Barnes (2000), Brooke (1984b), Campbell (1989), Clancey (1964b, 1985b, 1987a, 1990a), Colahan & Pringle (1998), Collar & Andrew (1988), Collar *et al.* (1994), Cooper (1985), Evans (2000a), Fishpool & Evans (2001), Ginn *et al.* (1989), Guy (1990), Harrison *et al.* (1997), Keith *et al.* (1992), Mackworth-Praed & Grant (1963), Maclean (1993a), McAllister (1994), Newman (1996), Osborne & Tiggar (1990), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Stattersfield & Capper (2000), Tarboton (1997, 2001), Tarboton *et al.* (1987), Vernon (1983a), Voelker (1999c), Wilson (1999).

46. Sharpe's Longclaw

Hemimacronyx sharpei

French: Pipit de Sharpe **German**: Zitronenpieper **Spanish**: Bisbita de Sharpe
Other common names: Sharpe's Pipit

Taxonomy. *Macronyx sharpei* Jackson, 1904, Mau Plateau, Kenya.
Genus apparently closely related to *Tmetothylacus* and *Macronyx*. Species previously placed in latter genus, a treatment still preferred by some authors; others regard it as belonging in *Anthus*, on basis primarily of plumage pattern and size. Appears, however, much closer to *H. chloris*, with which it probably forms a superspecies. Monotypic.

On following pages: 47. Cape Longclaw (*Macronyx capensis*); 48. Yellow-throated Longclaw (*Macronyx croceus*); 49. Fülleborn's Longclaw (*Macronyx fuellebornii*); 50. Abyssinian Longclaw (*Macronyx flavicollis*); 51. Pangani Longclaw (*Macronyx aurantiigula*); 52. Rosy-breasted Longclaw (*Macronyx ameliae*); 53. Grimwood's Longclaw (*Macronyx grimwoodi*).

Distribution. Highlands of W & C Kenya: Mt Elgon, and on both sides of Rift Valley on Uasin Gishu, Mau and Kinangop Plateaux, S slopes of Aberdares and N slopes of Mt Kenya. Possibly also on Ugandan side of Mt Elgon.

Descriptive notes. 16-17 cm. Small, slender longclaw with *Anthus*-like appearance. Adult male has lemon-yellow supercilium with small olive-brown streaks, pale creamy lores tinged yellow, ear-coverts with cinnamon-brown wash; narrow dark olive-brown moustachial stripe with line of small dark spots below; above, brownish-black with distinct cinnamon to yellow-ochre edgings of feathers, pointed uppertail-coverts very long; remiges olive-brown with paler or brighter edges, tertials brownish-black with buff to cinnamon fringes; upperwing-coverts dark olive-brown, fringed yellow, creamy white or buff; rectrices dark olive-brown, central four pairs fringed buff, T4 tipped white, next pair with white distal third and pale yellow edging of proximal half of outer web, outer pair white with dark olive-brown shaft and proximal third of inner web; chin to centre of belly deep lemon-yellow, blackish streaks on breast, flanks cinnamon with brownish-black streaks, thighs, side of belly and undertail-coverts pale yellow to pale horn, streaked olive-brown; underwing pale olive-brown, axillaries deep lemon-yellow, underwing-coverts white; iris brown to dark brown; upper mandible pale brown to blackish, lower mandible paler with dark tip; legs horn, flesh-coloured, brownish or yellow-ochre. Female is duller than male, has supercilium yellowish-buff, underparts duller yellow, tinged pale buff on breast, duller white on tail. Immature is paler above than adult, upperwing-coverts fringed whitish, buff supercilium, dull creamy whitish below, washed yellow on lower breast and centre of belly, breast heavily spotted olive-brown. Voice. Song, in flight or from perch, a series of thin, plaintive whistles rising in pitch, "yo yo teu-tee", "tyo tyo tew-tee", "tew tyo tew tee" or "yoo si-si-si-si", or more complex series of notes, e.g. "tee s-si ya yee yo-yo". Calls include high-pitched "tsip" or "tsit" in flight; also sharper "tswit", more plaintive "tweeeee", richer rising "yooee" or descending "seeoo", and thin "eeeu".

Habitat. Open, treeless, short and often tussocky grassland at 1850-3400 m, mostly below 2800 m; areas favoured may be moist, waterlogged or dry, depending on rainfall. On Kinangop Plateau, it was found to prefer short grass with tussocks rather than open short grass or long grass, and avoided non-grassland areas entirely. Occurs mostly at higher altitudes than *Macronyx croceus*, with little overlap between the two.

Food and Feeding. Insects, particularly grasshoppers (Orthoptera) and beetles (Coleoptera), also other small invertebrates. Forages in grassland; foraging range and rate of pecking for food items are higher in grass with tussocks than in other grassland habitats. Found singly, in pairs, or in family parties or groups of up to seven individuals.

Breeding. Laying during or just after rains, Mar-Jun and Sept-Oct, and in Dec. Monogamous; solitary nester, territorial. In brief aerial display, flies up from ground, sings more rapidly during descent. Nest a deep, well-constructed cup of dry grass, lined with rootlets, well hidden at base of grass tussock or herbaceous plant, in grass under small bush or under clod of earth, sometimes in excavated hollow. Clutch 2-3 eggs, mean 2·2; incubation and fledging periods not documented; injury-feigning display by adult with young in nest has been described.

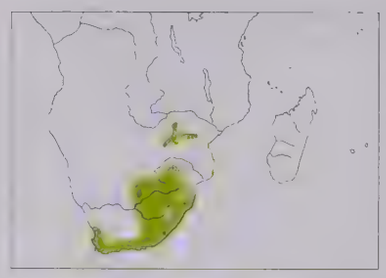
Movements. Sedentary; local movements may occur if habitat becomes very dry.

Status and Conservation. ENDANGERED. Restricted-range species: present in Kenyan Mountains EBA. Local and generally uncommon; in 1977 described as common on Kinangop and Mau Plateaux and around Nyahururu. Total range covers c. 2100 km², and global population thought to be greater than 10,000 individuals; great majority of population found on private land, outside protected areas. Mean home-range size 0·5 ha. Land-use changes, especially cultivation of grassland, planting of trees, and ploughing to remove tussock species, pose a serious threat; habitat loss has led to contraction of this species' range and decline in its numbers. Preservation and protection of suitable habitat considered essential in order to ensure its future survival.

Bibliography. Bennun (1999), Bennun & Njoroge (1999), Brown & Britton (1980), Clancey (1990a), Collar *et al.* (1994), Cooper (1985), Fishpool & Evans (2001), Keith *et al.* (1992), Lens, Bennun & Duchateau (2001), Lens, Duchateau & Bennun (1996), Lens, Muchai *et al.* (2000), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960), Muchai (1998, 2001), Muchai, Bennun & Lens (1998, 2001), Muchai, Bennun, Lens *et al.* (2002), Muchai, Lens & Bennun (2002), Muchane *et al.* (1996), Ndagn'ang'a, Mulwa & Gichuki (2003), Ndagn'ang'a, du Plessis *et al.* (2002), Short *et al.* (1990), Stattersfield & Capper (2000), Stevenson & Fanshawe (2002), Turner (1977a), Zimmerman *et al.* (1996).

Genus *MACRONYX* Swainson, 1827

47. **Cape Longclaw**



Macronyx capensis

French: Sentinelle du Cap **German**: Kappieper **Spanish**: Bisbita de El Cabo
Other common names: Orange-throated Longclaw

Taxonomy. *Alauda capensis* Linnaeus, 1766, Cape of Good Hope, South Africa.
Genus probably closely related to *Tmetothylacus* and *Hemimacronyx*. Races *stabilior* and *colletti* merged by some authors. Proposed race *latimerae* (Eastern Cape) included within *colletti*. Three subspecies currently recognized.

Subspecies and Distribution.
M. c. stabilior Clancey, 1952 - Zimbabwe (C plateau E to Inyanga Mts) and adjacent Mozambique.
M. c. colletti Schou, 1908 - extreme SE Botswana, E South Africa (Northern and C North-west Provinces S to N Eastern Cape), Swaziland and Lesotho.
M. c. capensis (Linnaeus, 1766) - coastal belt of SW & S South Africa.

Descriptive notes. 20-21 cm; male 49·2-55 g, female 45·2-52·2 g, unsexed 40-55 g. Large, chunky, short-tailed longclaw with reddish to orange throat, upright stance. Adult male nominate race has bright orange supercilium, white or pale yellow lores and line below eye, greyish-horn to dull cinnamon ear-coverts; forehead to mantle and scapulars dark olive-brown, pale feather fringes forming greyish (sometimes cinnamon) collar, back to uppertail-coverts greyish-horn to dull cinnamon; remiges dark olive-brown, edged orange-yellow, outer primary edged cream, secondaries tipped buff, tertials fringed buff to dull cinnamon; upperwing-coverts dark olive, fringed orange, orange-

yellow or cinnamon; rectrices dark olive-brown, central pair with narrow buff fringes, remainder with white at tip (becoming progressively greater towards outer pair) and with outer webs narrowly edged pale yellow to pale orange, outer pair with white outer web except at base; chin, throat, malar region and foreneck bright deep orange, bordered by brownish-black necklace, latter broadening in centre; centre of breast and belly orange-yellow, breast side (sometimes entire breast), flanks, thighs and undertail-coverts cinnamon to cinnamon-brown, breast side usually obscurely streaked olive-brown to buff-brown; underwing pale olive-brown, axillaries white, edged bright orange; iris hazel to dark brown; bill brown to blackish, greyish base of lower mandible; legs light brown, tinged flesh, reddish or yellow. Adult female is duller, has necklace browner and less well defined, breast and side of belly more greyish-horn to dull cinnamon. Juvenile has less orange-yellow below, narrower necklace; immature male has paler hindneck, darker feather centres above, pale cinnamon to creamy fringes forming bolder pattern on wing, throat patch creamy to orange, incomplete necklace, pale and duller orange-yellow centre of lower breast and belly, rest of underparts washed dull cinnamon to dark grey; immature female is paler below than young male. Race *colletti* is paler and brighter below than nominate, centre of breast and belly orange-yellow, breast side, flanks and thigh cinnamon to tawny-olive, sometimes pale grey on thigh and undertail-coverts; *stabilior* differs from previous in well-developed black feather centres on upperparts, is more rufous and less grey above, darker wings and tail, duller below, male has pronounced brownish suffusion on breast side. Voice. Song, in flight, a series of clear, piping, far-carrying "dweet" or "deweet" whistles, sometimes with added "meew", e.g. as "deweet, meew, deweet, meew". Calls include a series of clear, piping, far-carrying whistles "dweet" or "deweet", sometimes with an added "meew" rendered as "deweet, meew, deweet, meew". Calls include whistled "tsweet" from ground or in flight, also cat-like "meew" as alarm; also, harsh "chack", chirping "chi-rup" or "cheeerr-up", loud "choi", "chio", "chi-cho", "choik" and similar notes, often run together and given with other calls. May occasionally mimic other species.

Habitat. Favours short, usually dry, grassland in cool climates, but in some areas moist grassland, often near vleis and dams. In N occurs on montane grassland on highveld plateaux to c. 2300 m; in S on grasslands at lower altitudes, to sea-level in E & S South Africa. Also on pasture, fallow or cultivated land, and in extreme S on rocky seashores and in low fynbos. Often attracted to recently burnt ground, especially in non-breeding season. May occur alongside *M. ameliae* and *M. croceus* in parts of Zimbabwe and KwaZulu-Natal; occupies drier grassland than former, and found in areas with fewer intruding trees and bushes than those preferred by latter.

Food and Feeding. Food includes wide range of insects, both adults and larvae; also some grass seeds (Gramineae). Stomachs contained grasshoppers (Acrididae), beetles (Coleoptera) and stink-bugs (Pentatomidae). Other prey include termites (Isoptera), reduviid bugs (Hemiptera), and dipteran flies, including hippoboscids. Forages on ground in grassland, also on burnt ground; also in intertidal zone in S Cape region. Picks invertebrates from the ground; follows ploughs and associates with domestic stock, picking up disturbed insects. Uses its feet to scratch open termite tunnels. Chases moving insects; also catches them, notably termite alates, in the air, hawking out from a bush or small tree. Forages singly, in pairs or in small loose groups.

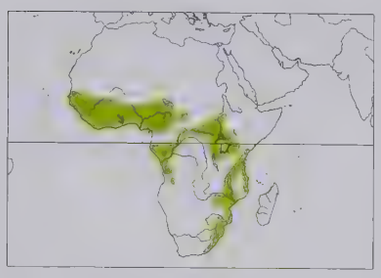
Breeding. Sept-Mar, mostly Nov-Feb, in Zimbabwe, and from Sept in Mozambique; in South Africa, Aug-Apr (mainly Nov-Jan) in N & E, and Jul-Dec (peak Aug-Sept) in SW. Monogamous; territorial. In display-flight, male rises to c. 10 m, sings while fluttering wings, drops back to ground. Nest a deep cup of grass, lined with finer grass and rootlets, built on ground close to or within grass tussock or well hidden in other dense vegetation cover. Clutch 2-5 eggs, mean 3; incubation and fledging periods not recorded.

Movements. Resident; some post-breeding altitudinal movements.

Status and Conservation. Not globally threatened. Fairly common throughout much of range; less abundant in Lesotho than in adjacent low-lying areas. Uncommon in lowlands and midlands of KwaZulu-Natal, where *M. croceus* is common. No evidence of any change in range or status in recent years, although at edges of its range, as in SE Botswana, contractions occur in some years.

Bibliography. Arnade (1981), Bowland (1984), Choate (1975), Clancey (1952c, 1959b, 1964b, 1968b, 1980, 1996), Cooper (1985), Dean (1987), Ginn *et al.* (1989), Gottschalk (1982, 1985), Harrison *et al.* (1997), Hewitt (1962), Hockey *et al.* (1989), Hunter (1985), Irwin (1981), Keith *et al.* (1992), Kopij *et al.* (2002), Langley (1973), Mackworth-Praed & Grant (1963), Maclean (1993a), Maclean & Prys-Jones (1988), Parker (1999), Parker & de Boer (2000), Pedersen (2000), Penry (1994), Rens (1999), Roberts (1913), Rowse (1996), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Swynnerton (1911), Tarboton (2001), Tarboton *et al.* (1987), Turner (1962), Voelker (1999a, 1999c).

48. **Yellow-throated Longclaw**



Macronyx croceus

French: Sentinelle à gorge jaune **German**: Gelbkehlpieper **Spanish**: Bisbita Gorgigualdo

Taxonomy. *Alauda crocea* Vieillot, 1816, Java; error = Senegal.
Genus probably closely related to *Tmetothylacus* and *Hemimacronyx*. May form a superspecies with *M. fuellebornii*. Plumage individually variable, and recognition of races often considered unwarranted; proposed race *hygricus* (Upper Guinea) included in nominate. Race *vulturnus* sometimes misspelt *vulturinus*. Three subspecies tentatively recognized.

Subspecies and Distribution.
M. c. croceus (Vieillot, 1816) - Senegambia E to Cameroon, W & S fringes of Chad, N & S Central African Republic, Gabon, NW & WC Angola, PRCongo, W, N & NE DRCongo, S Sudan, and Uganda and mesic areas of W & C Kenya S to Burundi and NW & N Tanzania (S to the Serengeti).
M. c. tertius Clancey, 1958 - coastal lowlands of Kenya and Tanzania.
M. c. vulturnus Friedmann, 1930 - C & S Tanzania, E Zambia (E of Luangwa Valley), Malawi, NE & C Zimbabwe and Mozambique S to SE South Africa.

Descriptive notes. 20-22 cm; male 43·8-57 g, female 43-51·6 g. Large, distinctive longclaw. Adult male nominate race has deep lemon-yellow supercilium, white area under eye, brown ear-coverts; olive-brown above, pale feather edges giving heavily streaked appearance, paler on neck, rump and uppertail-coverts, darker on scapulars and mantle; remiges and upperwing-coverts dark olive-brown with pale edges; rectrices dark olive-brown with pale shafts and fringes, T3 with distal quarter of inner web white, outer web white with narrow buff to pale yellow fringe, T4 similar but distal third of inner web white, T5 with distal half white, T6 with distal half white and outer web whitish with lemon-yellow edge; chin, throat, malar region and foreneck deep lemon-yellow, completely bordered by blackish band that broadens in centre of breast; rest of underparts deep lemon-

yellow, washed cream or buff, with variable amount of dull dark brown streaking; axillaries pale yellow, underwing-coverts white; iris brown, sometimes black, grey-brown or steel-blue; upper mandible brown to blackish, lower mandible grey, pale blue or, rarely, slate-green, sometimes tipped dark; legs pale brown to dull yellow, sometimes tinged flesh, straw or greenish, hind claw very long and curved. Female is duller than male, underparts often with buff or olive-yellow wash, necklace less well defined, usually narrower and dull dark olive-brown. Immature male is duller than adult, with darker fringes of upperpart feathers, yellow areas duller, washed with buff or olive-yellow, ill-defined broken necklace dark olive-brown, streaking below olive-brown and more extensive pale areas on tail duller, central rectrix with broad dull cinnamon fringe; immature female duller than young male, supercilium mainly dull buff, necklace of paler brown spots and streaks. Race *vulturnus* has longer bill than nominate, upperparts light greyish-brown with umber feather centres, throat, breast and abdomen lemon-chrome, flanks greyish-buff; *tertius* is greyer above than previous, lighter and clearer yellow below, bill shorter. Voice. Typical song, from perch or in flight, a rapid "tir-tri-tri-tri", the "tri" repeated up to c. 12 times, regionally variable, often preceded by whistled call notes. Commonest call a monotonous "tuewhee", "twee-eu", "meeeh" or "tsrrry", from top of bush or in flight; various multiple calls, e.g. descending far-carrying "te-ter-to" with last 2 notes repeated many times, whistled "torry teer-teer-eer-teer" with "teer" repeated, and "tirreeoo, trip-tritri"; also "tyoo-eoo", "tyo-éééoo" and variants, "twee-ee" and others; loud piping alarm "twip pipipipipipi" and hard "ker kwee-kwee-kwee" or rapid "keer keer keer".

Habitat. Dry grassland and cultivated open areas, scrubby grassland away from water, open clearings in miombo woodland (Zimbabwe) and in forest (W Africa), also airfields; also drier edges of wet grassland and swamps, as in S Sudan. Favours habitats having low trees and bushes for perches. To 1600 m in Zimbabwe, to 2350 m in Kenya; in South Africa occurs from sea-level to c. 900 m. In Kenya shares habitat (bushed and wooded grassland and ponds near Mombasa) with *M. aurantiigula*, but far more numerous than latter; found mostly at lower altitudes than *Hemimacronyx sharpei*. In Zimbabwe and NE South Africa (KwaZulu-Natal) occurs alongside *M. capensis* and *M. ameliae*, but different habitat preferences then evident.

Food and Feeding. Insects and other invertebrates, notably grasshopper adults and nymphs (Orthoptera), adult and larval beetles (Coleoptera) and moths (Lepidoptera), as well as mantids (Mantodea), ants (Hymenoptera), millipedes (Diplopoda), snails (Mollusca); also some plant material. Forages on ground. Usually in pairs or family parties.

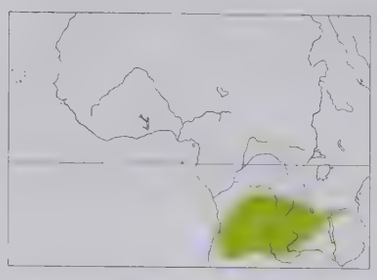
Breeding. Mainly during or just after rains, mainly May-Aug in W Africa, also Dec in Senegambia, Apr-Oct in Nigeria; Oct in Sudan; in all months but mostly during rains in Kenya, Mar-Nov (mostly in rains) in Uganda, Nov-Jun in Tanzania, Aug-Nov in DRCongo, Jun and Dec in Zambia, Nov-Apr in Malawi, Nov-May in Mozambique; Sept-Mar (before and during rains) in Zimbabwe, and in South Africa Aug-Apr (mostly Nov-Jan) in N and Oct-Feb in KwaZulu-Natal. Monogamous; territorial. Fluttering display-flight, with tail spread. Nest built by female, male in attendance, usually a deep cup of grass with lining of fine rootlets and fibres, well concealed under grass clump or against bush. Clutch 2-4 eggs, average 3; incubation mostly or solely by female, period 13-14 days; chicks fed by both parents, nestling period 16-17 days; fledgings attended by both sexes for up to 7 weeks or more.

Movements. Probably resident in many areas. Local seasonal movements noted in Sudan, Malawi and parts of South Africa; during survey work in S Africa, local variation in numbers from year to year also suggested some movement.

Status and Conservation. Not globally threatened. Widespread and not uncommon in suitable habitat through much of range, locally less common; scarce in Senegambia and rare in Mali. Common in several large protected areas, e.g. Serengeti National Park, in Tanzania. One old record from SE coast of Somalia, in 19th century; probably a wanderer from coastal Kenya. No imminent threats identified; could possibly become threatened locally if severe loss of habitat occurs.

Bibliography. Ash & Miskell (1998), Bannerman (1953), Barlow *et al.* (1997), Beesley (1972), Benson & Benson (1977), Benson *et al.* (1971), Carroll (1988), Cave & Macdonald (1955), Cheke & Walsh (1996), Christy & Clarke (1994), Clancey (1964b, 1968b, 1984e), Dean (2000), Demey & Fishpool (1994), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Evans & Balmford (1992), Farmer (1979), Gatter (1997), Ginn *et al.* (1989), Giraudoux *et al.* (1988), Gore (1990), Green (1983), Grimes (1987), Harrison *et al.* (1997), Hickling (1983), Hodgson (1971), Irwin (1981), Keith *et al.* (1992), Koster & Grettenberger (1983), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993a), Masterson & Child (1959), Medland (1992c), Nikolaus (1987), Parker (1999), van Perlo (1995), Rodwell (1996), Ryall (1991), Salewski (2000), Savalli (1991), Short *et al.* (1990), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Stevenson & Fanshawe (2002), Steyn (1996), Tarboton (2001), Thiollay (1985), Voelker (1999c), Wilkinson & Beecroft (1988), Zimmerman *et al.* (1996).

49. Fülleborn's Longclaw



Macronyx fuellebornii

French: Sentinelle de Fülleborn **German**: Fülleborn pieper **Spanish**: Bisbita de Fülleborn

Taxonomy. *Macronyx füllebornii* Reichenow, 1900, Unika Highlands, south-western Tanzania.
Genus probably closely related to *Tmetothylacus* and *Hemimacronyx*. May form a superspecies with *M. croceus*. Two subspecies recognized.

Subspecies and Distribution.
M. f. ascensi Salvadori, 1907 - Angola, C & S DRCongo, Zambia (W of Luangwa Valley) and extreme N Namibia; probably also extreme N Malawi.
M. f. fuellebornii Reichenow, 1900 - SW Tanzania.

Descriptive notes. 20 cm; male 53-64 g, female 46-60 g. Large, distinctive longclaw. Adult male has deep lemon-yellow supercilium, white to buff lores, cinnamon-brown ear-coverts; white or buffish-white line from lores to side of neck, sometimes to breast side; forehead to nape very dark olive-brown to brownish-black with slight scaled appearance, greyish collar; upperparts dark olive-brown to brownish-black, except for greyish back and rump sometimes tinged cinnamon; wings dark olive-brown to brownish-black, fringed bright yellow or yellowish-white to buff or greyish-horn; rectrices dark olive-brown, all except central pair tipped white, white area increasing in size towards outer feather, which has distal third white; chin, throat, malar region and foreneck deep lemon-yellow, bordered by blackish necklace from moustachial region downwards and across upper breast, where broadens in centre; rest of underparts dull lemon-yellow to buff, breast sometimes finely streaked dark; underwing pale olive-brown, axillaries white or yellowish-white; iris dark brown; upper mandible dark horn to black, lower mandible greyish or horn, tipped blackish; legs horn-coloured or brown, tinged yellowish, hind claw long and curved. Distinguished from similar *M. croceus* by having underparts suffused with buff, no streaking on side of breastband, less pronounced yellow supercilium, buff-brown flanks and undertail-coverts. Adult female has browner and narrower necklace. Immature is darker and duller above, duller and buffer below, necklace browner and narrower. Race *ascensi* is slightly larger than nominate, and has duller, less cinnamon rump. Voice. Song "tu-wee-ti-choo wee-ti-choo"; monotonous whistled "jee-o-wee", when perched or in flight; other recorded calls include mournful "peeeu", metallic "weee" or "wieh wrrit" and chirping "chwee".

Habitat. Moist highland grassland, wet plains and dambos, drainage lines in woodland, also dry grassland if near water, including near sewage-treatment works; occurs even in small areas of grassland, often with scattered trees and bushes. At 730-2450 m. Where overlaps in range with *M. ameliae* and *M. grimwoodi*, as in NW Zambia, occupies drier ground than those species.

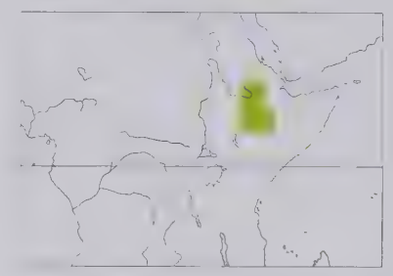
Food and Feeding. Insects, notably grasshoppers (Orthoptera) and beetles (Coleoptera); also spiders (Araneae). Forages on the ground; also catches termite alates (Isoptera) in flight. Occurs in pairs and family parties.

Breeding. Laying mainly during rains, Sept-Feb in most of range, but also in May in DRCongo, and occasionally Jun in Zambia; Nov-May in Tanzania. Monogamous; territorial. Nest a shallow, wide, neat cup of grass, lined with finer grass and rootlets, on ground close to or within grass tussock. Clutch 2-3 eggs, mean 2·7; incubation and fledging periods not recorded; nestlings fed by both parents; injury-feigning display observed when adult flushed from nestlings.

Movements. Resident; local seasonal movements, moving from drier grasslands to damper habitats in May-Sept. Nominate race recorded once in N Tanzania (Mbulu), far to NE of normal range.

Status and Conservation. Not globally threatened. Widespread and fairly common in Angola; common in highlands of Tanzania. Drainage of dambos and other wetlands may be a threat locally.

Bibliography. Anon. (1993), Aspinwall & Beel (1998), Benson, Brooke *et al.* (1971), Benson, Irwin & White (1959), Britton (1970), Brown & Britton (1980), Cooper (1985), Dean (2000), Dowsett & Dowsett-Lemaire (1978, 1997), Fishpool & Evans (2001), Keith *et al.* (1992), Lippens & Wille (1976), Lynes (1934), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993a), Newman (1996), Pedersen (2000), Rudebeck (1955), Short *et al.* (1990), Stevenson & Fanshawe (2002), Taylor (1983), Tree (1962).



50. Abyssinian Longclaw

Macronyx flavicollis

French: Sentinelle d'Abyssinie **German**: Goldhalspieper **Spanish**: Bisbita Abisinio
Other common names: Ethiopian Longclaw

Taxonomy. *Macronyx flavicollis* Rüppell, 1840, Simien Mountains, north Ethiopia.
Genus probably closely related to *Tmetothylacus* and *Hemimacronyx*. Monotypic.

Distribution. Mountains of N, C & SW Ethiopia

Descriptive notes. 20 cm. Adult male has saffron-yellow supercilium, paler and more buff to creamy behind eye, broad olive-brown eyestripe, buff to creamy ear-coverts; side of neck buff to cream; brownish-black above, paler on back, rump and uppertail-coverts, broad buff to cinnamon feather edgings producing striped appearance; primaries and secondaries olive-brown with pale or bright edgings, upperwing-coverts brownish-black, edged white, yellow, buff and cinnamon; rectrices dark olive-brown, all except outermost edged buff, T3 with small white tip, T4 with distal quarter of inner web and tip of outer web white, T5 with distal third of inner web and tip of outer web white, outermost rectrix with distal half of inner web and most of outer web white; chin, throat, malar region and foreneck deep saffron-yellow to orange-yellow, bordered by dark olive-brown moustachial stripe that joins blackish necklace of varying width, broader in centre; rest of underparts buff to cinnamon, paler on flanks and thighs, blackish-brown streaks on breast side, yellow wash on centre of belly; underside of remiges pale olive-brown with cinnamon tinge, axillaries white, underwing-coverts whitish with darker centres; iris dark brown; upper mandible black to grey, lower mandible grey; legs brown with flesh-coloured or yellow tinge, hind claw very long and curved. Adult female is paler and duller below than male. Immature has chin to neck buff or cinnamon, moustachial stripe browner, necklace browner and consisting of spots. Voice. Song, from perch or on the wing, a clear trill; has a piping call.

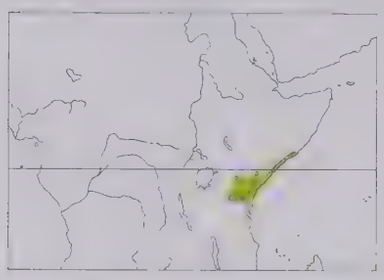
Habitat. Open grassland on high mountain plateaux; 1200 m to above 3000 m, mainly 1800-2750 m.

Food and Feeding. Insects and other invertebrates; no details of diet. Forages on the ground in grassland, by picking items from surface.

Breeding. Mainly Jun-Aug, occasionally in Feb. Nest a grass cup lined with fibre or horsehair, built on ground among young crops or in grass. Clutch 2-3 eggs. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Uncommon. Was considered abundant but local in 1950s and 1960s, and common and widespread from 1966 to 1977, but fewer were found in 1989; described as uncommon by ornithologists surveying Important Bird Areas during 1990s. Numbers may have been reduced through an expansion in area of cultivated land, and consequent increases in grazing pressure on remaining grassland, as a result of growth in human population.



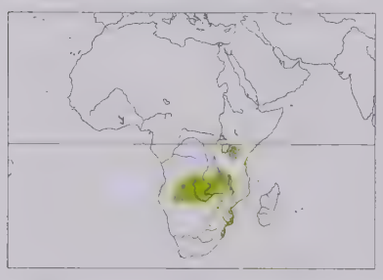
Bibliography. Ash & Gullick (1989), Benson (1946a), Collar *et al.* (1994), Cooper (1985), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fishpool & Evans (2001), Francis & Shirihai (1999), Keith *et al.* (1992), Mackworth-Praed & Grant (1960), Sinclair & Ryan (2003), Stattersfield & Capper (2000), Tilahun *et al.* (1996), Urban (1980), Urban & Brown (1971).

51. Pangani Longclaw

Macronyx aurantiigula

French: Sentinelle dorée **German**: Panganipieper **Spanish**: Bisbita de Pangani

Taxonomy. *Macronyx aurantiigula* Reichenow 1891, Pangani River, east Tanzania.
Genus probably closely related to *Tmetothylacus* and *Hemimacronyx*. May form a superspecies with *M. ameliae*. Birds from S Kenya sometimes separated as race *subocularis*. Monotypic.
Distribution. SE Somalia, SE Kenya (S on coast to Mombasa) and NE Tanzania (Arusha, W Tanga).



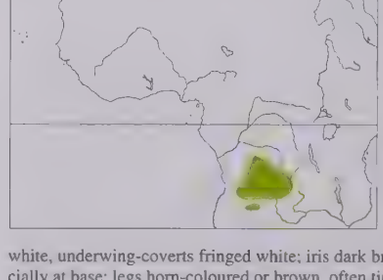
Descriptive notes. 19-20 cm; 36·6-43 g. Male has orange-yellow supercilium to above eye, white behind eye, cinnamon-brown ear-coverts; above, dark olive-brown to brownish-black with pale feather edges, giving scaly effect; wings olive-brown, outer edges of primaries fringed pale yellow, other feathers fringed buff; tail feathers dark olive-brown, central pair fringed buffish, rest with pale buff fringes and white tip, amount of white progressively increasing outwards, outermost rectrix mostly white with buff tinge; chin, malar region, throat and foreneck orange-yellow or deep yellow, entirely bordered by blackish moustachial stripe and necklace; breast side buff, centre of breast and belly, and sometimes thighs, deep yellow, belly side and undertail-coverts white to whitish-buff, brownish-black streaking on breast and flanks, olive-brown streaks on undertail-coverts; axillaries white; iris darkish brown; bill brown to black, lower mandible paler with dark tip; legs pale brown, tinged flesh. Distinguished from very similar *M. croceus* mainly by smaller size, more orange throat patch, narrower breastband, less extensive yellow below, more streaking below. Female has supercilium less yellow, is paler yellow below, necklace narrower. Immature is mainly buffish below, some yellow on breast, breastband broken and poorly defined. Voice. Song, from perch, a rapidly repeated descending "teeoo", or "syeet syeet syeet, churrie churrie which which which-which, tee-er, ee-er, tee-ur", each note repeated two or more times. Various calls given when perched or in flight, e.g. repeated high-pitched, plaintive "seeeeeee", repeated rising whistled "weee" or "ooeee" and rapid, chirping but musical "chrry"; anxiety call a plaintive "k-lee", given in flight during breeding season.
Habitat. Dry grassland with acacia trees (*Acacia*) and bushes, and coastal grassland; also on higher, moister grassland in NE Tanzania; open areas and light woodland in Somalia. Not associated with water. Generally below 1000 m; up to 1800 m in NE Tanzania. Slight overlap with *M. ameliae* on Ardai Plains, in Tanzania; also occurs together with *M. croceus* in coastal Kenya, both in parkland along lower R Tana and in acacia bush near Mombasa.
Food and Feeding. Prey includes insects, notably beetles (Coleoptera), grasshoppers (Orthoptera), termites (Isoptera), and small moths and their larvae (Lepidoptera); also spiders (Araneae) and snails (Mollusca). Forages mainly on the ground, but may snatch insects 1 m up in the air. Usually singly, in pairs or in trios.
Breeding. In all months except Aug and Oct in Kenya and Tanzania. Monogamous; solitary nester. Nest built by female, with male in attendance, a cup of dry grass, lined with fine rootlets and fibres, placed on ground in dense grass, or above ground in grass tussock with approach ramp. Clutch 2-4 eggs, mean 2·5; incubation, probably by female alone, 13 days; chicks fed by both parents, fledging period not documented; distraction display by male recorded.
Movements. Presumed resident in Somalia. Probably some local movements in Kenya; has been noted as absent from grassland near Mombasa in dry season (Jan-Apr), whereas it was found to be more common in Tsavo East National Park in wet season.
Status and Conservation. Not globally threatened. Uncommon in Somalia, occurring in narrow strip within 100 km of SE coast. Common in Kenya, where fairly common through year in Tsavo East National Park in areas with high grass cover. Recorded densities of 11 individuals/10 ha in grassland, 4 in bushed grassland, 2 in wooded bushed grassland and 2 in bushland; 2 birds/10 ha in riverine habitats. Locally common, and present in several protected areas, in Tanzania.
Bibliography. Ash & Miskell (1998), Beesley (1973), Bennun & Njoroge (1999), Britton (1980), Brown & Britton (1980), Cooper (1985), Fishpool & Evans (2001), Fuggles-Couchman (1984a, 1984b), Irwin (1957), Keith *et al.* (1992), Lack (1985, 1986), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960), Pearson (1983), van Perlo (1995), Pierce *et al.* (1977), Ryall (1991), Short *et al.* (1990), Stevenson & Fanshawe (2002), Wood (1988), Zimmerman *et al.* (1996).

52. Rosy-breasted Longclaw

Macronyx ameliae

French: Sentinelle à gorge rose **German**: Rubinkehlpieper **Spanish**: Bisbita Gorgirrosa
Other common names: Pink-throated/Rosy-throated Longclaw

Taxonomy. *Macronyx ameliae* de Tarragon, 1845, Durban, South Africa.
Genus probably closely related to *Tmetothylacus* and *Hemimacronyx*. May form a superspecies with *M. aurantiigula*. Validity of geographical races doubted by some authors, who prefer to treat species as monotypic. Three subspecies tentatively recognized.
Subspecies and Distribution.
M. a. wintoni Sharpe, 1891 - C & SW Kenya (C highlands, L Victoria basin, and Masai Mara) and N Tanzania (S to Serengeti and Ngorongoro Crater, E to L Manyara and Ardai and Sanya Plains).
M. a. altanus Clancey, 1966 - E & S Angola (E plateau), SE DRCongo and extreme SW Tanzania S to NE Namibia, N Botswana (Okavango Delta, Linyanti Swamp and Chobe floodplain), extreme NW Mozambique and extreme N & C Malawi (R Songwe mouth, and Lilongwe area); also on highveld of NE & C Zimbabwe.
M. a. ameliae de Tarragon, 1845 - coastal S Mozambique and NE South Africa (KwaZulu-Natal coast S to L St Lucia).



Descriptive notes. 19-20 cm; male 30·3-39·8 g, female 30·8-34 g. Distinctive, slender, long-tailed longclaw with pink throat. Male has whitish to buff supercilium, pinkish in front of eye, buffish-white lores and cheeks, cinnamon-brown ear-coverts; blackish above, feathers edged cinnamon, buff or whitish, neck side pale cinnamon with dark olive-brown streaking; wings olive-brown, remiges edged whitish, pinkish or buff, coverts variously edged pink, red, orange, white and buff; tail dark olive-brown, central four feather pairs edged buff to white, T4 with small white tip, T5 with distal third or more white, outermost rectrix mostly white; chin, malar area, throat and foreneck orange, pink or red, bordered by blackish moustachial stripe that meets blackish necklace on upper breast, breastband broadest in centre; breast side buff or whitish with blackish streaking, lower breast and belly as throat but paler; flanks, thighs and undertail-coverts buff, streaked brownish black; underwing-coverts white; iris dark brown; upper mandible brownish or grey, lower mandible paler, particularly at base; legs brownish, sometimes tinged yellow or orange. Distinguished from *M. grimwoodi* mainly by more deeply coloured throat patch and belly, black breastband. Female differs from male in being paler and more buff, less red, below, necklace and breastband reduced to disjointed streaking. Juvenile has buff scalloping above, and is buff without breastband below; male may take two years to acquire adult plumage; immature female is less red below than adult, white on rectrices duller. Race *altanus* is smaller and shorter-billed than nominate, has dusky wedge on inner web of outer rectrix extending over proximal two-thirds; *wintoni* is similar to previous but less heavily streaked black above, forehead and crown with narrower streaks, rump and uppertail-coverts less heavily spotted black, feather edgings above paler, less heavy streaking on breast side and flanks. Voice. Song, in flight or from top of bush, a uniform "wee-tjihwee-tjih", or a series of squeaky whistled notes with wheezing final syllable, "pink-pink-pink-zheenk". Anxiety or alarm call a sharp "chuitt" or more metallic "tyang"; other calls include plaintive double "chuit chuit"; seldom calls in flight.
Habitat. Short tussocky, moist or wet grassland, either permanently or seasonally flooded, near swamps, marshes, floodplains of rivers, pans and other open water; also flooded cultivation, fallow rice fields and wet pasture on coast. From sea-level to 2200 m. Inhabits wide range of grassland types, from *Panicum repens* beds on Zambia-Zimbabwe border (L Kariba) to fine grasses such as *Sporobolus* by vleis and lakes; usually in treeless grassland, but in Zambia occurs in areas with scattered small acacia trees (*Acacia*), and in parts of Okavango Delta (Botswana) in areas with small tree islands. In Zambia, occupies wet grassland close to L Kariba whereas *M. fuellebornii* favours slightly higher, drier grassland nearby; usually in wetter habitats than those preferred by *M. croceus* and *M. capensis*, but sometimes occurs with those species on drier ground.
Food and Feeding. Larval and adult insects up to size of grasshopper (Orthoptera); also, small frogs occasionally taken. Forages on the ground, picking items from surface; also catches termite alates (Isoptera) in flight.
Breeding. Laying mainly during or after rains: Apr-Jun and Dec in Kenya, and Dec-Jan, Mar and May in Tanzania; Sept, Nov-Dec, Feb-Mar and Jun in Zambia, and Dec-Jan in DRCongo and Malawi; Nov-Apr in Zimbabwe, Mar in Mozambique and Sept-Apr in South Africa; birds in breeding condition in Oct in Botswana. Monogamous; territorial. Male sings in display-flight, rising high and circling or hovering, with legs dangling; or from top of tree or bush. Nest built by female, male in attendance, a deep, compact cup of dry grass, lined with rootlets and fine dry grass, placed on or above ground beside or between grass tussocks; may have a short entrance run through grass. Clutch 2-4 eggs, mean 2·8; incubation by female, for 13-14 days; nestlings fed by both parents for up to 16 days, male may deliver food to female, which passes it to chicks; distraction display by adult recorded during or just after nestling period, calls and hovers or flutters, legs dangling, above intruder, makes short flights to lead intruder away.
Movements. Mainly sedentary, locally nomadic; seasonal movements in response to rainfall and the burning or drying-out of grassland also recorded. Atlas surveys in S Africa suggest local movements, although apparent seasonality in occurrence possibly due to fact that the species may be more conspicuous early in breeding season. In wetlands with seasonal variations in water levels, however, breeding habitat deserted during times of high flooding or of drying-out. Recent sporadic records at L Kariba perhaps indicative of extensive nomadic movements.
Status and Conservation. Not globally threatened. Locally common to uncommon; not uncommon in Angola; uncommon in Kenya. Distribution disjunct. Has apparently disappeared from parts of S Mozambique, and fewer than 100 individuals estimated to survive in area S of R Save; suggested that the species has been adversely affected by human disturbance of marshland along coast, and that it is threatened in that region. Has also disappeared from parts of KwaZulu-Natal (South Africa), and concern has been expressed here about effects of encroachment of industry onto its grassland habitats; regarded as "Vulnerable" in South Africa. Elsewhere, drainage of wetlands a potential problem. In S Africa, highest reporting rates during 1997 surveys were from Okavango Delta (Botswana), where habitat largely secure, although increased human settlements and grazing by domestic livestock in N of delta, together with burning on floodplains, are of some concern. Formerly extended farther S in NE Botswana; contraction of range may be due to series of low-rainfall years in early 1990s.
Bibliography. Benson & Benson (1977), Benson *et al.* (1971), Berruti (1992), de Boer & Bento (1999), Britton (1970), Brooke (1984b), Brown & Britton (1980), Chapin (1953), Clancey (1964b, 1967b, 1996), Cooper (1985), Cruikshank (1963), Dean (1971, 2000), Ginn *et al.* (1989), Harrison *et al.* (1997), Irwin (1981), Keith *et al.* (1992), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1960, 1963, 1973), Maclean (1993a), Medland & Karcher (1990), Parker (1999), Penry (1994), Short *et al.* (1990), Siegfried *et al.* (1976), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Skinner (1989), van Someren (1956), Stevenson & Fanshawe (2002), Steyn (1996), Tarboton (2001), Zimmerman *et al.* (1996).

53. Grimwood's Longclaw

Macronyx grimwoodi

French: Sentinelle de Grimwood **German**: Grimwoodpieper **Spanish**: Bisbita de Grimwood

Taxonomy. *Macronyx grimwoodi* Benson, 1955, Chitunta Plain, Mwinilunga District, north-west Zambia.
Genus probably closely related to *Tmetothylacus* and *Hemimacronyx*. Monotypic.
Distribution. S DRCongo S to WC & E Angola and extreme NW Zambia.

Descriptive notes. 19·5-21 cm. Male has cinnamon supercilium and malar area, black lores and moustachial stripe, cinnamon-brown ear-coverts; feathers of upperparts, including wings, cinnamon to tawny with blackish centres; rectrices dark olive-brown, T3 with white tip of inner web, T4 with white distal third of inner web, T5 with distal half of inner web white, outermost rectrix with inner web white, outer web pale brownish-grey; chin, throat and foreneck reddish to orange, rest of underparts dull cinnamon with tawny-buff wash, sometimes pinkish on centre of belly; breast, flanks, thighs and undertail-coverts streaked blackish; axillaries white, underwing-coverts fringed white; iris dark brown; bill dark horn, lower mandible paler, especially at base; legs horn-coloured or brown, often tinged pinkish or reddish. Differs from *M. ameliae* in having paler pink on underparts confined to throat and not surrounded by black, breast streaked,

flanks more narrowly and sparsely streaked, also larger size, longer and heavier bill. Female has paler chin and throat than male. Immature undescribed. Voice. Little known; aerial song said to be a series of whistled notes, "wee-wrrit, wee-wrrit" and the like, similar to that of *M. fuellebornii*.
Habitat. Moist short grass on plains, in river valleys, along drainage lines (dambos) and in grassy hollows, between 800 m and 1500 m. Sometimes occupies the wettest habitats when occurring alongside *M. ameliae* and *M. fuellebornii*, with latter in driest places; often, however, no obvious ecological segregation between present species and *M. fuellebornii*.
Food and Feeding. Little information. Apparently feeds on small insects such as beetles (Coleoptera), grasshoppers (Orthoptera) and pentatomid bugs (Hemiptera).
Breeding. Nest containing 2 eggs found in DRCongo in Feb (rainy season); not described. No other information.
Movements. Believed to be resident.
Status and Conservation. Not globally threatened. Data-deficient. Little recent information available on population size or threats to its habitats.Considered to be not uncommon in Angola; locally common in NW Zambia, where three pairs were found on Kamunoka Plain (Zambezi District) in Oct 1997, and estimated 1 pair/300 m on Chitunta Plain. Research and fieldwork required in order to establish main details of this species' ecology and biology, as well as its precise distribution and population level.
Bibliography. PLATE 76

inches 3
cm 8

Genus *DENDRONANTHUS* Blyth, 1844

54. Forest Wagtail
Dendronanthus indicus

French: Bergeronnette de forêt **German**: Baumstelze **Spanish**: Lavandera Forestal
Other common names: Tree Wagtail

Taxonomy. *Motacilla indica* J. F. Gmelin, 1789, India.
Relationships uncertain; sometimes placed in genus *Motacilla*. Monotypic.
Distribution. Breeds from Russian Far East (S Ussuriland) S to SE China (S to SW Sichuan, N Guizhou and N Fujian) and S Japan (SW Honshu, NW Kyushu); also sporadically in NE India (Cachar Hills, in Assam). Winters in S & SE Asia.

Descriptive notes. 16-18 cm; 14-17 g. Small motacillid with distinctive wing and breast patterns. Adult has prominent, long, whitish supercilium, occasionally dark moustachial and malar stripes; upperparts greenish-tinged brownish-grey, uppertail-coverts blackish or blackish-brown; remiges blackish, edged whitish, yellowish-white bases forming patch on wing; lesser wing-coverts brownish-grey, tinged greenish, median and greater coverts blackish with yellowish-white tips (two wingbars); central pair of rectrices brownish-grey, tinged greenish, next four pairs dull blackish-brown, T4 sometimes tipped white, outer two pairs whitish with dark bases; underparts whitish, sometimes washed faintly yellow and buffy on flanks, two black crescent-shaped bands on upper breast (lower one sometimes broken), broader in centre; underwing-coverts whitish, underside of remiges dark grey with whitish bases (forming wingbar); iris dark brown; upper mandible dark grey, lower mandible pinkish, sometimes tipped dark; legs pale dull pinkish, hind claw short and curved. Sexes alike. Immature is browner, less green, above than adult, breastbands brownish-black and narrower, lower one completely or partially missing. VOICE. Song a disyllabic "tsi-fee" repeated 4-5 times; call a metallic "pink" or double "pink-pink".
Habitat. Forest, secondary growth and open woodland, to 1800 m. Wide variety of forests, both deciduous and evergreen, including mixed and sometimes pure coniferous forest, also dense riverine forest; in Russia, favours relatively young well-lit oak (*Quercus*) forest and mixed hardwood forests with oak predominant. Often along streams and tracks. In winter, also wooded cultivation and well-shaded coffee and cardamum plantations, parkland, glades and clearings in mixed bamboo jungle, mangroves. Also visits cattle yards and mudflats for foraging on passage and in winter; roosts communally in sugar cane, reeds and mangroves, in Thailand often with *Motacilla flava*.
Food and Feeding. Food consists of small invertebrates, such as ants (Hymenoptera), beetles (Coleoptera), small grasshoppers (Orthoptera), butterflies (Lepidoptera), cicadas (Cicadidae) and other hemipterans, and other insects, also spiders (Araneae), small molluscs and worms (Annelida). Forages mostly on the ground, running about quietly on shady forest paths or on mulch-covered forest floor; also in trees, running along horizontal boughs and up and down at a steep angle. When disturbed usually flies to perch in tree, sways tail and rear body from side to side. Singly or in pairs.
Breeding. Breeds mainly Apr-Jun. Monogamous; territorial. Nest built by female, accompanied by male, a compact firm cup of twigs, leaves, fine grasses and rootlets matted together with moss and cobwebs, draped with lichen to match surroundings, lining of hair, wool, fur or moss roots, placed c. 2-7 m above ground, sometimes higher, in small tree, often on horizontal branch or in crotch, usually by a stream. Clutch 4-5 eggs; incubation by female alone, fed on nest by male; chicks fed by both sexes; incubation and fledging periods not documented.
Movements. Migratory. Winters in India (mainly SW & NE), Bangladesh and Sri Lanka, and from Myanmar and S & SE China S to Greater Sundas; occasionally farther N, in Korea and SW Japan. Leaves breeding areas from late Aug, present on non-breeding grounds late Sept/Oct to Apr; arrival in breeding areas mostly in May. Accidental in Mongolia, Pakistan, Nepal, Philippines. Vagrants recorded a few times in Middle East.
Status and Conservation. Not globally threatened. Locally common, both in breeding and in non-breeding areas. First bred in Japan in early 1970s; previously only very rare migrant. Only occasional breeder in NE India, on the Laisung stream in N Cachar Hills (Assam); suspected breeding in SW Myanmar (Arakan Yomas) unconfirmed, believed unlikely. Very common in Thailand (especially in S) outside breeding season. No potential threats identified; no evidence that deforestation has led to any decline in population of this species.
Bibliography. Genus *MOTACILLA* Linnaeus, 1758

55. White Wagtail
Motacilla alba

French: Bergeronnette grise **German**: Bachstelze **Spanish**: Lavandera Blanca

Other common names: Black-backed/Japanese Pied/Kamchatka Pied Wagtail (*lugens*); Black-eared/Hodgson's Wagtail (*alboides*); Indian White Wagtail (*dukhunensis*); Masked Wagtail (*personata*); Moroccan Wagtail (*subpersonata*); Pied/British Pied Wagtail (*yarrellii*); Streak-eyed Wagtail (*ocularis*); Swinhoe's Wagtail (*baicalensis*); Amur/White-faced Wagtail (*leucopsis*)

Taxonomy. *Motacilla alba* Linnaeus, 1758, Sweden.
Thought to form a superspecies with *M. maderaspatensis*, *M. grandis* and *M. aguimp*, all of which formerly often regarded as races of present species, and with recently described *M. samveasnae*; some recent analyses of mitochondrial DNA, however, suggest that *M. aguimp* possibly more distantly related to that group. Geographical variation marked and complex. Races often divided into four groups on basis mainly of breeding range: "nominate group" (including also *yarrellii*, *persica*, *dukhunensis*, *personata*, *baicalensis*), "*alboides* group" (with *leucopsis*), "*lugens* group" (with *ocularis*), and single-taxon "*subpersonata* group". In addition, several races sometimes regarded as separate species, but widespread intergradation occurs where races meet, and frequent co-occurrence evident in non-breeding quarters; in particular, *lugens* and *personata* often ranked as full species, but former appears to intergrade and interbreed with both *leucopsis* and *ocularis*, and latter with *dukhunensis*, *alboides* and *baicalensis*. Moreover, the described taxa *persica* and *dukhunensis* may be only inter-racial hybrids, perhaps better included within nominate. Proposed race *frontata* (described from Xiamen, SE China, where probably only migrant) provisionally included in *leucopsis*, though possibly of hybrid origin. Other named races include *forwoodi* (described from Abd al Kuri I, W of Socotra), included in nominate; and *albula* (Khasi Hills, in NE India), considered inseparable from *alboides*. Eleven subspecies currently recognized.
Subspecies and Distribution.
M. a. alba Linnaeus, 1758 - breeds SE Greenland, Iceland, Faeroe Is and throughout continental Europe (has bred Britain and Ireland) E to Urals, Turkey and Levant; winters in S part of range and S to W & E Africa, Arabia and SW Asia.
M. a. yarrellii Gould, 1837 - breeds Britain and Ireland, possibly also N parts of W Europe; partial migrant, winters S to NW Africa.
M. a. dukhunensis Sykes, 1832 - breeds from C Russia (Ural Mts E to Taymyr Peninsula) S to Caucasus, NW Iran, Kyrgyz Steppes and foothills of Altai Mts; winters Middle East E to Indian Subcontinent.
M. a. ocularis Swinhoe, 1860 - breeds N & NE Siberia (E from Taymyr Peninsula and R Yenisey, S to Lensk region, Stanovoy Mts and N Kamchatka) and extreme NW USA (W Alaska); winters S Asia E from NE Indian Subcontinent.
M. a. subpersonata Meade-Waldo, 1901 - NW Africa (W Morocco).
M. a. persica Blanford, 1876 - NC & W Iran (S Elburz Mts, Zagros Mts).
M. a. personata Gould, 1861 - breeds C Asia from Transcaspia and N Iran E to S Russia (W Sayan Mts), W Mongolia, extreme NW China (NW & W Xinjiang) and S to N Afghanistan, N Pakistan and Kashmir; winters Iran and E Arabia E to Indian Subcontinent.
M. a. baicalensis Swinhoe, 1871 - breeds SC Siberia (upper R Yenisey E to Stanovoy Mts) S to Mongolia and NE China (NE Nei Mongol); winters N India E to SE China and C Indochina.
M. a. lugens Gloger, 1829 - breeds SE Russia (from S coasts of Sea of Okhotsk, Sakhalin, C Kamchatka and Commander Is) S to N Korea and Japan; winters Myanmar E to SE China, Taiwan and S Japan.
M. a. leucopsis Gould, 1838 - breeds C & E China (Qinghai E to Heilongjiang and W Zhejiang, S to N Guangxi and N Guangdong), Russian Far East (Amurland, Ussuriland), Korea and SW Japan (SW Honshu, N Kyushu); winters S Asia E from N India.
M. a. alboides Hodgson, 1836 - breeds Himalayas (E from NE Pakistan), S China (S Xizang, S & SE Qinghai E to S Shaanxi, S to Yunnan and Guizhou), N Myanmar, extreme N Laos and extreme N Vietnam; winters in foothills and S to Bangladesh and N Thailand.

Descriptive notes. 16·5-18 cm; male 20-24·6 g, female 17·6-21·9 g (to 27·9 g when laying). Male nominate race in breeding plumage has mid-crown to nape and hindneck black, chin and throat black, rest of head white; mantle and scapulars to uppertail-coverts grey; wings greyish-black, tertials broadly edged white, broad white fringes on median and greater wing-coverts (two white wingbars); central pair of rectrices black, narrowly fringed white, next three pairs black, outer two pairs white with dark wedge on inner web; black of throat extends down to breast; rest of underparts white, washed greyish on breast side and flanks; iris blackish-brown; bill and legs black. Breeding female differs from male in slightly duller head pattern, sometimes some grey on crown, usually some grey on nape, thus less contrast with mantle, often some pale spots on throat. Both sexes non-breeding have olive-grey wash on crown and nape, white chin, throat and upper breast with some black mottling. Immature has brownish-grey head, dusky moustachial stripe, greyish-white chin and throat, rest of underparts also greyish-white, sometimes tinged buffy, with narrow dark grey-brown gorget. Races differ mainly in colour of back and/or rump and pattern of black and white on head (all have white forehead) of male, to which following details refer, females often difficult to ascribe to race: *yarrellii* has black back; *subpersonata* has more black on head, extending to lores, cheeks and ear-coverts and meeting black of chestband, with short supercilium, moustachial stripe and patch on neck side white; *ocularis* differs from nominate in blackish eyestripe (may be indistinct), more white on wing-coverts (often white wing panel); *lugens* has jet-black back, black eyestripe, white chin (sometimes speckled blackish), white remiges and primary coverts with some blackish on distal parts of primaries, outer rectrix usually all white, inner web of T4 often white; *leucopsis* has jet-black back, white chin and upper throat, white breast side, remiges with narrow white tips, secondaries broadly edged white, greater coverts and tips of medians white, outer rectrix all white; *baicalensis* resembles previous, but back grey, slightly less white on head, less white in wings; *alboides* has black back, much black on head and neck, white confined to forehead and area around eye, large white wing panel, white edges of secondaries and tertials; *personata* resembles previous, but upperparts grey, not black; *dukhunensis* has upperparts on average somewhat paler, more blue-grey, than nominate, more white on wing-coverts (sometimes forming unbroken panel); *persica* is generally intermediate between previous two, much individual variation. VOICE. Song a warbling twitter of repeated slurred "zit", "psit", "ziti", "zilipp", "zittip" and similar contact calls. Call, in flight, a high-pitched "chissik" or "tscizzic" or monosyllabic "zit" or "psit" (nominate race), or "ziti" (*baicalensis*), or more shrill "tschizzik" or "tissick" or "chisk" (*yarrellii*); "pii-tup" or "piiup" like sparrow (*Passer*) chirp in Iran (*personata*); twittering noises at roost.

On following pages: 56. White-browed Wagtail (*Motacilla maderaspatensis*); 57. Japanese Wagtail (*Motacilla grandis*); 58. Mekong Wagtail (*Motacilla samveasnae*); 59. African Pied Wagtail (*Motacilla aguimp*).

Habitat. Very wide variety of non-forested wet and dry habitats, including seashores, rocky or sandy upland rivers and slow-moving lowland rivers, lakeshores, farmland, gardens, parks, short grassland such as that found in vicinity of factories in towns and cities; frequently around human habitations in towns and villages. On migration and in winter months, also edges of reservoirs, lakes, ponds and sewage works, wells in deserts, irrigated fields and rice fields, as well as in wide variety of open short grasslands and other sites in towns and villages, at campsites and on beaches. Largely restricted to vicinity of running water throughout year in NW Africa (race *subpersonata*). Breeds from lowlands to mountains, to 5000 m in Himalayas; recorded on passage to 5700 m in W China (S Xizang). Roosts communally in trees, sometimes in reedbeds; often on or inside buildings, such as factories and glasshouses, in urban areas.

Food and Feeding. Food includes wide range of small terrestrial and aquatic invertebrates, ranging from weevils (Curculionidae) and other beetles (Coleoptera), dragonflies (Odonata), adult and larval flies (Diptera), termites (Isoptera) and ants (Hymenoptera) to spiders (Araneae), small snails (Mollusca), crustaceans and worms (Annelida), as well as fish fry; crumbs and other household scraps also taken. Observed to take fly maggots from carcasses. In one study in England, dipterans comprised 96·7% of 4654 items from faeces collected by pools, and the birds also took mainly dipterans (87·5% of 779 items) when foraging at dung pats; small beetles made up the rest of the diet in both cases. In Russia, dipterans again accounted for more than 50% of items in one study, although other aquatic invertebrates and beetles formed a major part of the diet in other studies. Forages while walking, readily exploiting lawns, bare areas, roads and pavements, roofs and other open areas. Picks at items on the ground or darts forwards (run-picking) to snatch prey; jumps up to take insects in the air or makes short flights to catch aerial prey (flycatching). Sometimes wades in shallow water, picking invertebrates from the surface or in mud, or hovers over water or vegetation to snatch prey. Also forages amidst seaweed along tideline. May follow ploughs on farmland. Singly or in pairs; frequently in loose flocks when on migration, and also at rich winter feeding areas and at roosts; some, especially adult males or pairs, maintain individual and regular feeding areas during winter months.

Breeding. Mostly early Apr to Aug, starting later in N; late Apr to mid-Jul in S & SE Europe, Apr-Jun in Morocco and May to early Aug in S Asia (*alboides*); up to three broods. Monogamous; strictly territorial, and highly aggressive towards both conspecifics and congeners. Nest, built by both sexes, a rough cup of twigs, grass stems, leaves, rootlets and mosses, lined with hair, wool or feathers, sited in hole or crevice in riverbank, wall or bridge, and often in building or even in machinery. Clutch 3-8 eggs, usually 4-6; incubation by both parents, female taking greater share and she alone sitting at night, period 11-13 days, sometimes up to 16 days; chicks fed by both parents for 11-16 days; fledglings fed by parents for up to 1 week.

Movements. Most races regular long-distance migrants; others partial migrants or largely resident. In Europe, some W & S populations of nominate race and of *yarrellii* resident, but N populations of latter are partial migrants, moving S & SW to as far as Iberia and NW Africa in autumn; mostly resident in NW Africa (*subpersonata*). All N & E populations move S after breeding. Nominate race regularly migrates S into S & SW Europe. N half of Africa (mainly in the arid N bordering the Sahara) and S Asia; in Africa winters S to Sahel zone and to Uganda and Kenya, and a few as far S as Malawi, but rarely occurs S of Tanzania; fairly common passage migrant through Somalia and a regular winter visitor in small numbers to S Sudan. Asian populations winter in Arabia (nominate, *personata*) and across S parts of Asia, where up to six races found together in winter quarters from Indian Subcontinent E to SE China; *ocularis* and *leucopsis* move farthest S, to Malay Peninsula and Philippines, and former recorded also in W North America (S to Mexico); accidental in Australia (*baicalensis*, *lugens*, *leucopsis*) and Seychelles (nominate or *dukhunensis*). Migrants leave breeding grounds Aug-Oct, return mainly Mar-Apr, often not until late May in N of range. In Iranian mountains (*persica*) and in E Himalayas to S China (*alboides*) generally shorter movements, involving post-breeding descent to lower elevations.

Status and Conservation. Not globally threatened. Generally common throughout its breeding and non-breeding ranges; locally very common or abundant. Estimated European population over 12,000,000 breeding pairs; population generally stable, although sometimes temporary declines following severe winters. Breeding density has been correlated variously with food supply and with availability of enclosed nest-sites found in human settlements; in Europe average densities c. 1-4 pairs/km², but up to 43 pairs/km² in rural villages in Germany. No comparable data for Asia, but appears to be generally common and widespread; race *lugens* common in Japan, where winter roosts of 2000-7000 recorded. Has adapted well to man-made environments, and exploited opportunities for nesting and roosting offered by buildings and other artificial structures, and for foraging by lawns, roads and open surfaces. A highly successful species.

56. White-browed Wagtail

Motacilla maderaspatensis

French: Bergeronnette indienne **German**: Mamulastelze **Spanish**: Lavandera India
Other common names: Large Pied Wagtail

Taxonomy. *Motacilla maderaspatensis* J. F. Gmelin, 1789, Madras, Tamil Nadu, India.
Formerly regarded as a race of *M. alba*. Thought to form a superspecies with that and with *M. grandis*, *M. samveasnae* and *M. aguimp*, although recent analyses of mitochondrial DNA suggest that last species possibly more distantly related to this group. Birds from Punjab region, described as race *kangrae*, generally considered indistinguishable from other populations. Monotypic.

Distribution. N Pakistan E in Himalayan foothills to Bangladesh, probably to Arunachal Pradesh, and S through most of peninsular India.

Descriptive notes. 21-24 cm; 30-36 g. Rather large wagtail. Male has all-black head except for broad white supercilium from bill to rear of ear-coverts, very thin white crescent below eye; upperparts mostly black, median and greater wing-coverts mostly white, primary coverts black, edged white; remiges blackish, tipped white, primaries with basal two-thirds also white, secondaries with basal half of outer webs white, much of closed wing appearing white (large white wing patch in flight); tail black, outer two rectrices white with inner webs edged black; throat and side of neck to upper breast black, rest of underparts white, greyish wash on flanks, underwing-coverts whitish; iris dark brown; bill and legs blackish. Female is usually greyer or duller black above, primaries browner. Immature has supercilium shorter (starts from above eye), black areas of upperparts greyish-brown, breast side tinged greyish-buff, rest of underparts white; bill more brownish, pinkish base of lower mandible. Voice. Song a clear, high-pitched jumble of loud pleasant whistling notes; call a loud "chiz-zit", given in flight.

Habitat. Watercourses. Favours streams and rivers, especially smooth-flowing rivers with rocks and stony shoals, but occurs along any watercourse; also at irrigation tanks, lakes, pools and wells, and sometimes in paddyfields and on lawns. To 1500 m, mainly below 915 m in N, sometimes to 1700 m in Nepal; to 2200 m in hills in S India. Outside breeding season roosts in flocks in tamarisks (*Tamarix*) or reeds, often with other wagtail species and with swallows (Hirundinidae).

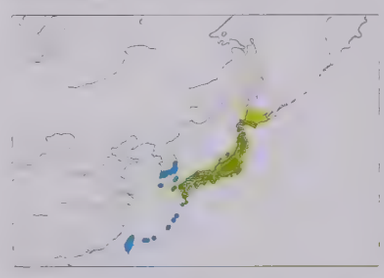
Food and Feeding. Diet consists of insects, especially small coleopterans (e.g. Tridactylinae), grasshoppers (Orthoptera) and dragonflies (Odonata), also snails (Mollusca) and other small items. Picks prey items from sand and among pebbles, usually along water's edge, while walking or running.

Breeding. Laying Mar-Jun, rarely Sept-Oct, in N, and Dec-Jun in S, coinciding with low water levels in dry season. Monogamous; territorial. Nest built by both sexes, a bulky structure of roots, grass and various materials, neat cup lined with hair or wool, placed near water in variety of sites, including hole in bank, wall or building, ledge under bridge, crevice in tree trunk or rock face, in clump of vegetation on wall or rock, in disused nest of dipper (*Cinclus*); also in river ferryboat in constant use. Clutch 3-5 eggs, usually 4; incubation and fledging periods not documented; young cared for by both sexes.

Movements. Mainly resident, living in pairs throughout year. Descends from highest elevations to lower levels after breeding. Some dispersal; rare non-breeding visitor in Sri Lanka.

Status and Conservation. Not globally threatened. Fairly common to locally common, and widespread; scarce in Bangladesh. Probably occurs in NE India (Arunachal Pradesh, N Assam), but status there uncertain. Reports from S China (Yunnan) in 19th century considered of doubtful validity. Unlikely to be at any major risk in immediate future; nevertheless, construction of new dams and reservoirs, leading to submergence of lowland rivers, could place populations at risk locally.

Bibliography. Ali (1969, 1996), Ali & Ripley (1998), Ali *et al.* (1996), Alström & Mild (2003), Anon. (1998d), Barua & Sharma (1999), Chakravarthy & Tejasvi (1992), Chanda (1998), Daniels (1997), Gokula & Vijayan (1997), Grewal (1995), Grimmett *et al.* (1998, 2000), Harrison (1999), Hasan (2001), Henry (1998), Inskipp & Inskipp (1991, 1993), Inskipp *et al.* (1996), Javed & Rahmani (1998), Kazmierczak (2000), Kirkpatrick (1954b), Lamsfuss (1998), Mahabal & Lamba (1987), Majumdar *et al.* (1992), Mason & Lyczynski (1980), Mohan (1997), Mukherjee (1995), Phillips (1978), Pittie (1997), Purandare (2002), Ripley (1982), Roberts (1992), Shrestha (2000), Srinivas & Subramanya (2000), Sugathan & Varghese (1996), Voelker (2002), Whistler (1923).



57. Japanese Wagtail

Motacilla grandis

French: Bergeronnette du Japon **German**: Japanstelze **Spanish**: Lavandera Japonesa
Other common names: Japanese Pied Wagtail

Taxonomy. *Motacilla grandis* Sharpe, 1885, Japan.
Formerly treated as conspecific with *M. alba*, but the two breed sympatrically in Japan. Both thought to form a superspecies with *M. maderaspatensis*, *M. samveasnae* and *M. aguimp*, although recent analyses of mitochondrial DNA suggest that last species possibly more distantly related to this group. Monotypic.

Distribution. Breeds in Japan; non-breeding visitor to Korea (has bred) and S to Taiwan.

Descriptive notes. 21-23 cm. Male has forehead, supercilium, chin and very thin white crescent below eye white; rest of head, down to breast, and upperparts black; primaries mostly white, dull blackish distally, edged and tipped white, secondaries all white, median and greater wing-coverts mostly white (wing appearing mostly white both when closed and in flight); tail black, outer two rectrices white with black edging on inner webs; underparts below breast white, underwing-coverts white; iris dark brown; bill and legs blackish. Female is more greyish-black above, diffuse dark markings on remiges, dark tips of white primary coverts. Immature has head grey, tinged brown, supercilium off-white and often indistinct, upperparts pale grey, blackish uppertail-coverts. Voice. Song, by both sexes (male in most months, female mainly Feb), comprises basic notes and short phrases combining different notes, e.g. "ji", "ju", "joi", "byu", "bui", "pouyu", "fi", "gi" and similar; simple song a repetition of same phrase, grading into more complex songs, continuing for 40-60 seconds without pause, e.g. as "tztzui tztzui tztzui pitzpitz tztzui pitzpitz-bitbitzeen bitbitzeen-bitbitzeen tztzui tzgichigi jijijiji". Call in flight, on take-off or when landing, "bi" or "ji"; warning calls when predator near nest include "pitzuin" or "pisui" and longer rattling chatter.

Habitat. Riparian habitats, dry riverbeds and rice fields, along large rivers with gravelly shores; also around open spaces in towns. More in coastal areas in winter. Sea-level to 1500 m. Overlap in habitat with *M. alba* (race *lugens*) in breeding season.

Food and Feeding. Arthropods. In urban areas, prey largely flies (Diptera), especially craneflies (Tipulidae), forming 88% of items fed to chicks; spiders (Araneae) made up much of remainder of food, although some mole-crickets (*Gryllotalpa*) taken and these were important by weight. Away from urban areas, along rivers, mayflies (Ephemeroptera) and stoneflies (Plecoptera) more important than dipterans in diet. Forages mainly by walking and picking prey from the ground.

Breeding. Laying Mar-Jul; 2-3 broods. Monogamous, occasional bigyny recorded; normally solitary, and territorial, aggressive towards conspecifics and congeners, notably *M. alba* (race *lugens*).

Nest built by both sexes, taking c. 16 days (but as little as 4-5 days for later nests), a cup of leaves, rootlets and grass stems, lined with finer material, typically sited in vegetation on riverbank or on gravel shoal, in towns frequently on or under roof of building, less commonly on branches of tree or in wood pile. Clutch 4-7 eggs, mainly 5; incubation by both sexes, period 11-13 days; chicks brooded mainly by female, fed by both sexes, both also remove faecal sacs, nestling period 13-15 days; fledglings accompanied by and fed by parents for c. 15 days, gather in communal roosts from mid-summer, later joined there by adults of population.

Movements. N populations (N Hokkaido) appear to move S & W in autumn; non-breeding visitor to Ryukyu Is, scarce but regular visitor to Korea Dec-Mar, and occasional winter visitor to Taiwan and coast of E China.

Status and Conservation. Not globally threatened. Common and widespread in S Hokkaido, Honshu, Kyushu and Shikoku, and on Sado I (off W Honshu). Less common in N & C Hokkaido, where largely replaced by *M. alba* (of race *lugens*); recent expansion of latter has led to more overlap and, probably, increased competition. Status in Korea uncertain; pair bred in 1966, and thought by some to be a rare resident; possibly local and uncommon breeder in extreme S and on E coast, but more study needed.

Bibliography. Alström & Mild (2003), Austin (1948), Austin & Kuroda (1953), Brazil (1991), Étchécopar & Hüe (1983b), Gore & Won Pyongoh (1971), Haneda & Shinoda (1969), Higuchi & Hirano (1981, 1983a, 1983b, 1989), Higuchi & Nakamura (1983), Hirano (1980, 1981, 1985), Hirano & Higuchi (1986), Inskipp *et al.* (1996), Kanouchi *et al.* (1998), Meyer de Schauensee (1984), Nakamura (1982, 1985), Nakamura *et al.* (1984), Ohsako (1989), Ohsako & Yamagishi (1989), Shigeta (1995, 1996b), Sonobe (1982), Uchida & Nagata (2000), Won Pyongoh (1993), Yoon Mooboo (1992).

58. Mekong Wagtail

Motacilla samveasnae

French: Bergeronnette du Mékong **German**: Mekongstelze **Spanish**: Lavandera del Mekong

Taxonomy. *Motacilla samveasnae* Duckworth *et al.*, 2001, San River, Stung Teng province, Cambodia.

Recently described species. Thought to form a superspecies with *M. alba*, *M. maderaspatensis*, *M. grandis* and *M. aguimp*, although recent analyses of mitochondrial DNA suggest that last species possibly more distantly related to this group. Monotypic.

Distribution. Lower R Mekong and tributaries in extreme S Laos and NE Cambodia (upstream from Kampi), also marginally in adjacent parts of Thailand and Vietnam.

Descriptive notes. 17-17·5 cm. Male has forehead to nape blackish, long, broad white supercilium, very thin white crescent below eye, blackish lores, ear-coverts and neck, white triangular patch on lower neck side; upperparts blackish-brown; remiges white proximally, dark distally, lesser wing-coverts brownish-black, outer median coverts white with blackish bases, inner ones blackish with white tips and edges, greater coverts blackish with white tips (two white wingbars); tail blackish, tinged brownish, outer two rectrices white with blackish base of outer web and edge of inner web; chin and throat white, broad blackish U-shaped breastband, rest of underparts white, tinged grey; iris dark brown; bill black; legs greyish-black. Distinguished from *M. aguimp* by smaller size, proportionately longer bill, more extensive white outer edges of primary feathers. Adult female is paler and greyer above than male, with less white in wing. Immature is browner above. Voice. Simple song a brief rapid series of rather thin, high-pitched, often rather harsh notes, all notes different and phrases or rattles rare, each series interspersed by pause of 4-6 seconds or more, same series may be repeated several times; resembles song of *M. grandis* but with fewer harsh notes, lacks drawn-out rolls of *M. maderaspatensis*, lacks frequent phrases and rattles of *M. aguimp*. Complex song a drawn-out, rapid ramble of notes, many as in simple song, but with high proportion of harsh, drawn-out notes and buzzing sounds like those of e.g. Eurasian Siskin (*Carduelis spinus*), and resembling that of *M. grandis*. Flight call a short, sharp, rather harsh "dzeer", sometimes doubled or repeated several times, resembles that of *Anthus spinoletta* and *A. petrosus*, also of *M. grandis* but lower-pitched and less clipped; softer, lower-pitched versions given when perched or in flight.

Habitat. Broad lowland rivers; requires braided sections of river with swift-flowing water, and with distinctive mosaic of sandbars and gravel shoals and numerous emergent rocks and bushes ("channel mosaic"). Appears to shun exposed areas such as sandbars and earth banks, as well as higher islands with vegetation resembling that of adjacent floodplain. Most records are from rivers more than 100 m wide.

Food and Feeding. Little known. Diet probably small arthropods. Forages regularly within tops of emergent bushes, walking along branches and picking small food items from these or from the leaves. Foraging behaviour outside breeding season not known.

Breeding. Breeds Feb-Apr, in later part of low-flow season. No other information.

Movements. Little known. Appears to leave breeding habitats during season of high water flow, when channel mosaics submerged; only one record from R Mekong outside breeding period.

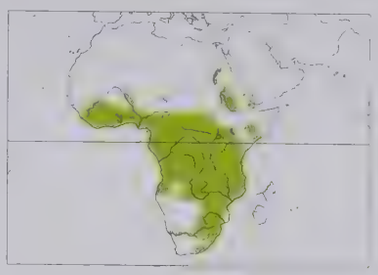
Status and Conservation. Not globally threatened. Initially described as recently as 2001. Numbers considered currently healthy in Cambodia, but status in Laos uncertain; at least three pairs found in Vietnam (R Serepok, in Yok Don National Park) in 2003. Occurs in several protected areas in Laos and Cambodia, and potentially in Thailand. Channel mosaic considered less vulnerable than other river-channel habitats, but new dams pose one of greatest threats. Recent proposal to blast and dredge R Mekong for the Lancang-Mekong Navigation Channel Improvement Scheme, if carried out, would place this species at serious risk; blasting and clearance of rapids, shoals and reefs to facilitate navigation would directly affect river habitats in China, Myanmar, Laos and Thailand, and also indirectly affect river life in Cambodia and Vietnam. Following numerous objections sent to governments of China, Myanmar, Laos and Thailand, pointing out inadequacies of an environmental-impact assessment and the ecological consequences if the scheme were to go ahead, the project did not start in 2002; continued monitoring of the situation essential. In addition, fieldwork is required in order to establish details of this species' ecology and behaviour.

Bibliography. Alström & Mild (2003), Anon. (2001h, 2002e, 2003d), Davidson *et al.* (2001), Duckworth *et al.* (2001), Pitches (1997), Scott & Pitcher (2002).

59. African Pied Wagtail

Motacilla aguimp

French: Bergeronnette pie **German**: Witwenstelze **Spanish**: Lavandera Africana
Other common names: African Wagtail



Taxonomy. *Motacilla aguimp* Dumont, 1821, Lower Orange River, South Africa.

Thought to form a superspecies with *M. alba*, *M. maderaspatensis*, *M. grandis* and *M. samveasnae*; recent analyses of mitochondrial DNA, however, suggest that it is possibly more distantly related to this group, and may be a sister-taxon to a group containing *M. alba* (with race *lugens*), *M. flava*, *M. citreola* and *M. cinerea*. Two subspecies recognized.

Subspecies and Distribution.

M. a. vidua Sundevall, 1850 - Sierra Leone and S Mali E to S Sudan and NW & E Kenya, S to Angola, N & E Botswana and E South Africa (S to Eastern Cape); also lower Nile Valley (S from S Egypt), and discontinuously N & E Sudan, W Eritrea, NW, NE & S Ethiopia, and S Somalia.

M. a. aguimp Dumont, 1821 - R Orange and R Vaal drainages in S Namibia, C South Africa and Lesotho.

Descriptive notes. 20 cm; male 22-33 g, female 23-30 g. Male nominate race in breeding plumage has broad white supercilium from bill base to well behind eye, squarish white patch on side of neck; centre of forehead to nape, also lores, subocular area, ear-coverts and vertical band on neck side black; mantle, scapulars and back black, rump greyish-black, uppertail-coverts black, lateral ones with white outer webs; primaries black with narrow white tips, large white area on both webs at base, secondaries black, broadly tipped white, outer web edged white, tertials black with outer webs broadly edged white; alula, primary coverts and lesser wing-coverts black, median and greater coverts white; tail black, central pair of feathers sometimes with wide white edging, outer two pairs white, T5 with black edging on inner web; chin to uppermost breast white, broad black pectoral band narrower at side, black blotching on side of breast and flanks, rest of underparts white; underwing-coverts white; iris dark brown; bill and legs black. Differs from similar *M. samveasnae* in somewhat larger size, proportionately shorter bill, less white on outer edges of primaries. Non-breeding male has black of upperparts replaced with slate-grey. Breeding female has dark areas less intensely black; in non-breeding plumage upperparts are dark olive-grey. Immature has black of adult plumage (except remiges and rectrices) replaced with dark olivaceous grey-brown, white replaced with buffy white, greater and median primary coverts white with buffy tips. Race *vidua* differs from nominate in narrower, better-defined breastband, lacks black blotching on breast side and flanks, has outer rectrix entirely white and adjacent one with less black. Voice. Song a sustained melodious series of whistling and piping notes, "weet-weet, wip-wip-wip, weet, wee-wee" and so on, likened to song of Atlantic Canary (*Serinus canaria*); imitates other species, including Common Bulbul (*Pycnonotus barbatus*) and Chattering Cisticola (*Cisticola anonyma*). Call a high-pitched sharp "tweet" or "chizzit", and more liquid rapid trisyllabic "quick-quick-treeet", "twee-twee-twee" or "tseet-tseet-tseet" with final note very high, or a whistled thin but loud "tuwhee".

Habitat. In humid tropical regions occurs near human habitations, as at farms, in villages, on roofs and roads in towns and cities, in parks and on garden lawns, as well as around reservoirs, lakes, coastal lagoons, sewage ponds, and on sandy banks or rocky areas along or in rivers. In drier areas more restricted to perennial rivers with rocks and sandbanks and to other permanent waterbodies, such as reservoirs. Sea-level to moderate elevations; to 3000 m in E Africa. Communal roosts in non-breeding season in trees, on buildings, even on boats.

Food and Feeding. Diet includes wide variety of small terrestrial and aquatic invertebrates, mainly insects. Recorded items include adult and larval flies (Diptera), beetles (Coleoptera), grasshoppers (Orthoptera), dragonflies (Odonata), ants (Hymenoptera), termites (Isoptera), butterflies (Lepidoptera), crustaceans, worms (Annelida). Small fish also taken; and household crumbs and scraps eaten. Forages by walking and picking, or darting forward to snatch prey on the ground or from low vegetation (run-picking); also by jumping up to snatch an insect, or by aerial fly-catching. Occasionally hovers over water to pick insects from surface. Outside breeding season, flocks of up to 100 sometimes congregate at favoured feeding areas, e.g. sewage farms, individuals and small groups foraging in close proximity to one another.

Breeding. Starts to breed prior to rains and continues into wet season: mostly Feb-May in W Africa, Oct-Apr in Nigeria, Aug and Dec-Feb in Gabon, probably all months in DRCongo; most or all months (mainly Feb-Dec) in E Africa, Dec-Oct in coastal Kenya and S Somalia; Feb-May and Aug-Nov (mainly Mar, Sept, Oct) in Malawi, and Feb-Dec (mainly Sept) in Zambia; in all months except Jan (peak Aug-Oct) in Zimbabwe; all months except May, mainly before and at start of rains, peak in Sept-Oct, in South Africa; usually 2-3 broods, in Kenya up to seven recorded in a season. Monogamous; solitary, and territorial, very aggressive towards conspecifics, sometimes also towards other species, e.g. *M. cinerea* and Common Sandpiper (*Actitis hypoleucos*). Nest, built by both sexes, a bulky cup of grass, stems, rootlets, leaves, downy seeds and feathers, occasionally seaweed and coconut fibres incorporated, lined with grass, hair, feathers or fine rootlets, placed on ground in grass tussock or other vegetation, in riverbank, in flood debris, in crevice or on ledge in cliff or in house roof or outbuilding, sometimes on boat. Clutch 2-7 eggs, usually 3-4; incubation by both sexes, mainly by female, period 13-14 days; chicks fed by both sexes, nestling period 15-16 days; juveniles fed by both parents for c. 2 weeks after fledging. Nests parasitized by Red-chested Cuckoo (*Cuculus solitarius*), Diederik Cuckoo (*Chrysococcyx caprius*) and Jacobin Cuckoo (*Clamator jacobinus*).

Movements. Largely resident; some movements, but not fully understood. Much local movement thought to take place in many countries, but data for S Africa reveal little evidence of large-scale seasonal movements; an uncommon vagrant in Botswana away from N & NE breeding areas. Non-breeding visitor to Pemba I and Zanzibar, off NE Tanzania; recorded also in W Chad (L Chad), on São Tomé and in SW South Africa.

Status and Conservation. Not globally threatened. Common and widespread in much of range, and generally tame and confiding; common to uncommon in W Africa. Locally common in S Sudan, but absent in extreme SE, the Sudd and the region NW of Wau. Uncommon in Somalia, only 19 records to 1991, along lower R Juba; three old records on coast at Baraawe, somewhere on R Shabeelle and on Ethiopian side of border. Widespread and common in Kenya (except N & NE); very common in Malawi below 1500 m and in Viphya Mts (at 1830 m) and Nyika Plateau (at 2240 m). Appears to have declined as a breeding bird during 20th century along Nile Valley in Egypt. Over much of S Africa has possibly benefited from construction of dams and from creation of lawns and ponds in parks and gardens, although drying-up of rivers through overabstraction may have caused some local declines.

cm 10

60. Yellow Wagtail

Motacilla flava

French: Bergeronnette printanière **German**: Schafstelze **Spanish**: Lavandera Boyera
Other common names: Yellow(ish)-crowned Wagtail (*flavissima*); Grey-headed/Dark-headed Wagtail (*thunbergi*); Blue-headed (Yellow) Wagtail (*flava*); Iberian/Spanish (Yellow) Wagtail (*iberiae*); Ashy-headed Wagtail (*cinereocapilla*); Egyptian Yellow Wagtail (*pygmaea*); Black-headed Wagtail (*feldegg*); (Eastern) Yellow-headed/Yellow-browed Wagtail (*lutea*); Sykes's Wagtail (*beema*); White-chinned Wagtail, Turkestan Black-headed Wagtail (*melanogrisea*); Alaska (Yellow) Wagtail (*tschutschensis*); White-headed Wagtail (*leucocephala*); Green-crowned/Green-headed/Kuril (Yellow) Wagtail (*taivana*); Short-tailed Grey-headed Wagtail, Siberian (Yellow) Wagtail (*simillima*)

Taxonomy. *Motacilla flava* Linnaeus, 1758, southern Sweden.
Relationships uncertain. Has been thought to form a superspecies variously with *M. citreola*, or with *M. capensis*, or with those two together with *M. flaviventris*, but recent molecular-genetic studies indicate that none of these arrangements is tenable. Taxonomy complex, and much further research needed. Recent studies, using mitochondrial DNA, suggest that races may represent three separate species, one in NE (based on *tschutschensis*), another in extreme SE (based on *taivana* and *macronyx*), and a third in W & C (based on nominate race); moreover, they also indicated that the NE group was closest to E nominate form of *M. citreola* and the SE group closest to W race (*werae*) of latter; other researchers, however, consider those two races of *M. citreola* to be inseparable in terms of morphology. In addition, several races (especially *lutea*, *feldegg* and *taivana*) have often been treated as separate species by various authors. Taxonomy is further complicated by the fact that some races are known to hybridize on fairly regular basis, thus confusing the picture with regard to distributional limits. Race *plexa* is perhaps indistinguishable from *thunbergi*; *simillima* possibly better included in *tschutschensis*, and *angarensis* in latter or in *macronyx*; and *melanogrisea* possibly inseparable from *feldegg*. Race *alakulensis* (from SE Kazakhstan) synonymized with *thunbergi*, *alascensis* (W Alaska) with *tschutschensis*, and *aralensis* (Aral Sea) and *raddei* (Transcaspia) with *feldegg*; proposed race *zaissanensis* (L Zaisan, in E Kazakhstan) is apparently an intergrade or hybrid form, and other suggested races *superciliaris*, *dombrowskii* and *perconfusus* similarly represent inter-racial hybrids. Pending further research, and bearing in mind above-mentioned details, all forms traditionally considered to belong in present species are treated as such and listed below. Seventeen subspecies currently recognized.
Subspecies and Distribution.
M. f. flavissima (Blyth, 1834) - breeds Britain and adjacent coastal Europe; winters Africa.
M. f. thunbergi Billberg, 1828 - breeds Scandinavia E to NW Siberia; winters mainly sub-Saharan Africa and across S & SE Asia.
M. f. flava Linnaeus, 1758 - breeds N & C Europe (S from S Scandinavia) E to Urals; winters sub-Saharan Africa.
M. f. iberiae Hartert, 1921 - breeds Iberia, SW France and NW Africa (S to islands of Banc d'Arguin, in Mauritania); winters W & NC Africa.
M. f. cinereocapilla Savi, 1831 - breeds Italy (including Sardinia and Sicily) and Slovenia; winters Mediterranean coast and CW Africa (Mali E to L Chad).
M. f. pygmaea (A. E. Brehm, 1854) - resident in Egypt (delta and S along R Nile).
M. f. feldegg Michahelles, 1830 - breeds SE Europe (former Yugoslavia E to S Ukraine), S to Turkey, E Mediterranean, Iraq, W Caspian, Iran and Afghanistan; winters Africa (mainly Nigeria E to Sudan and Uganda).
M. f. lutea (S. G. Gmelin, 1774) - breeds SW Russia (between lower R Volga and R Irtysh, S from Kazan' and Perm') and N Kazakhstan (E to L Chany and L Zaysan); winters Africa and Indian Subcontinent.
M. f. beema (Sykes, 1832) - breeds from upper R Volga E to SW Siberia, S to N Kazakhstan and Altai Mts, also W Himalayas (Ladakh, possibly also N Kashmir); winters mainly Indian Subcontinent, also Arabia and E Africa.
M. f. melanogrisea (Homeyer, 1878) - breeds Volga delta and SW Kazakhstan S to NE Iran and Afghanistan; winters mainly S Asia E to W Nepal, possibly also NE Africa.
M. f. plexa (Thayer & Bangs, 1914) - breeds N Siberia (R Khatanga E to R Kolyma); winters India and SE Asia.
M. f. tschutschensis J. F. Gmelin, 1789 - breeds NE Siberia and extreme NW North America (N & W Alaska, extreme NW Canada); winters mainly SE Asia (E to Philippines, S to Indonesia).
M. f. angarensis (Sushkin, 1925) - breeds S Siberia and W Transbaikalia S to N Mongolia; winters SE Asia (Myanmar and Thailand E to SE China).
M. f. leucocephala (Przevalski, 1887) - breeds NW Mongolia, extreme NW China (N Xinjiang) and adjacent parts of former USSR; winters probably mostly in India.
M. f. taivana (Swinhoe, 1863) - breeds SE Siberia, Amurland, Sakhalin and N Japan (N Hokkaido); winters Myanmar, S China and Taiwan S to Greater Sundas, Philippines and Wallacea.
M. f. macronyx (Stresemann, 1920) - breeds SE Transbaikalia E to Amurland and Ussuriland, S to NE Mongolia and C Manchuria; winters SE Asia S to Malay Peninsula and SE China.
M. f. simillima Hartert, 1905 - breeds Kamchatka, N Kurils and Commander Is, and possibly Pribilofs and Aleutian Is; winters SE Asia and Philippines S to Sundas and Wallacea, and N Australia.

Descriptive notes. 16·5 cm; male 12·3-26·4 g, female 11·2-22·6 g, much variation with season, time of day and locality. Male nominate race in breeding plumage has blue-grey forehead to nape and hindneck, often somewhat darker ear-coverts, long narrow white supercilium from bill base to nape side, dark stripe through eye, thin whitish submoustachial stripe; upperparts greenish-tinged olive-brown; remiges blackish, tertials fringed yellow or buffy white, wing-coverts blackish, fringed and tipped greenish-yellow (two wingbars); tail brownish-black, fringed olive, outer two feather pairs wholly or largely white; chin, throat and underparts bright yellow, some green on breast side and flanks, sometimes an indistinct olive or greenish necklace; underwing-coverts white; iris dark brown; bill greyish to black; legs slate-grey to black. Male non-breeding plumage is similar to breeding female, browner above, yellower rump, wingbars less contrasting, dark necklace more obvious. Female in breeding plumage has duller, less contrasting head pattern, greyish or grey-brown crown, brownish cheeks, upperparts browner, less yellow; paler and less uniformly yellow below, especially throat, breast buffish and variably spotted dark brown, often forming necklace. Non-breeding female is duller than male, paler below, often with more obvious necklace. Immature resembles non-breeding female, may be greener above. Races vary mainly in colour and pattern of head of breeding male, whereas females and immatures often very difficult to assign to race (even when seen together in non-breeding areas): *flavissima* male has bright yellow head, more olive on hindcrown, nape, hindneck and ear-coverts, female is darker, browner, above and paler yellow below than nominate; *lutea* male has whole head yellow, female is similar to previous; *iberiae* male resembles nominate but has chin and throat white, not yellow, female has darker cheeks and whiter chin; *cinereocapilla* male is like previous but white supercilium absent or inconspicuous, female resembles previous; *pygmaea* male has dark grey crown and ear-coverts, white chin and throat, lacks supercilium, female is similar to last; *beema* male resembles nominate but forehead, crown, hindneck and ear-coverts pale ash-grey and supercilium broader, female has broader and longer supercilium; *leucocephala* male has white head except for yellow centre of throat and sometimes greyish hindneck, female variable, resembles either nominate or previous; *thunbergi* male has dark slate-grey forehead, lores, forecrown and ear-coverts shading to dark blue on hindcrown to hindneck, yellow centre of chin and throat, some birds with white rear supercilium and some with white stripe below ear-coverts, female differs from nominate in having darker crown, cheeks and upperparts, less obvious supercilium and darker necklace; *plexa* male has darker ear-coverts and lores and is more greyish on mantle than previous, female resembles dull male or is like nominate but darker; *tschutschensis* male differs from last in paler grey head, long white supercilium, sometimes blackish ear-coverts, female is variable, sometimes as nominate but with darker and greyer ear-coverts, or like dull male; *simillima* male differs from last in being brighter yellowish-green above, brighter below and generally lacking necklace, female resembles last; *angarensis* male has dark slate-grey crown and loral stripe, slate-black ear-coverts, narrow white supercilium, female resembles previous; *macronyx* male differs from previous in paler ear-coverts, no supercilium, brighter green mantle, deeper yellow underparts, more conspicuous wingbars, female is similar but duller or like nominate but darker and without supercilium; *taivana* male has long, broad deep yellow supercilium, dark ear-coverts and lores, yellow throat, dull greenish crown, nape and upperparts, female is variable, similar to washed-out male, with greenish-brown ear-coverts, paler and slightly narrower supercilium; *feldegg* male has glossy jet-black from forehead to hindneck and down to ear-coverts, sharply demarcated from yellow chin and throat, yellow-tinged wingbars, female has black mottling on head; *melanogrisea* male resembles last but has white stripe separating yellow throat from black cap, upperparts brighter green, sometimes an indistinct olive or greenish necklace, female is similar to last. Voice. Song, from perch (often bush or fence post) or in flight, a very brief trill or twitter of 2-3 notes, e.g. "srrii-srrríť". Call a shrill, drawn-out monosyllabic "tsweep", "chreep", "tseer" or "psie", occasionally disyllabic "tsi-weep", "sree-sreeh" or "tuwiet wheet". Some variation in both calls and songs among races, e.g. *feldegg* call harsher "szrrie".
Habitat. Variety of damp or wet habitats with low vegetation, from damp meadows, marshes, waterside pastures, sewage farms and bogs to damp steppe and grassy tundra; also large clearings in forest in N of range. In non-breeding season uses similar habitats, especially pasture and damp grassland, also cultivations; roosts in reedbeds and similar tall vegetation. Most races forage primarily in damp grassland or on relatively bare open ground at edges of rivers, lakes and other wetlands, but also in dry grassland and cereal crops; often feeds around herds of cattle and other large mammals, especially when on migration and in non-breeding season, and in African winter quarters associates with herds of game in rather open acacia (*Acacia*) savanna. Some differences in habitat preferences among races: *feldegg*, for example, favours swamps, lakesides and other wet places in winter quarters in Africa, and in Ethiopia often associated with edges of streams and rivers with fast-flowing water, whereas nominate race then occurs in drier habitats with grazing stock or game. Mainly lowlands to c. 1000 m, but in Caucasus locally up to 2500 m; breeds at 3600-4500 m in Ladakh.
Food and Feeding. Diet includes wide variety of terrestrial and aquatic invertebrates; also some plant material, especially seeds. Invertebrates range from small flies (Diptera), bugs (Hemiptera), beetles (Coleoptera), grasshoppers (Orthoptera), butterflies (Lepidoptera), cockroaches (Blattodea), termites (Isoptera) and ants (Hymenoptera) to crustaceans; dragonflies (Odonata) sometimes important by mass. In African winter quarters, sample of stomach contents dominated in terms of bulk by adult beetles 3-5 mm long, and larvae of beetles and lepidopterans present in small numbers; bugs, beetles, ants and grasshoppers were numerically the most important prey in another study. Small flies were found to be most important elsewhere, as at L Chad and L Victoria. Some berries, e.g. from saltbush (*Salvadora persica*), and other plant material also taken. Forages by picking items from the ground or from water while walking; also run-picks, and makes short flights to catch insects in the air, over water or from vegetation. Occasionally hover over vegetation to take prey. Frequently associates with domestic stock, especially cattle, both in summer and in winter, also with wild game in winter quarters; takes advantage of insects attracted by the animals and their dung and disturbed by their grazing activity. Often in small to large or very large flocks outside breeding season; single individuals often defend a feeding territory throughout winter, and small flocks may also do so.
Breeding. Apr-Aug, varying with latitude; 1-2 broods. Monogamous; solitary, territorial breeder. Nest, built mainly by female, a grass cup lined with hair, placed on or close to ground in shallow scrape. Clutch 4-6 eggs; incubation by both sexes, female taking greater share, period 11-13 days; chicks fed by both parents, nestling period 10-14 days; fledglings remain with parents for several weeks. Nests sometimes parasitized by Common Cuckoo (*Cuculus canorus*). Adult seen to feed Crested Lark (*Galerida cristata*) fledgling in S France.
Movements. Almost wholly migratory; resident in Egypt (*pygmaea*), probably at least partially so also in NW & W Africa (*iberiae*). W populations winter throughout sub-Saharan Africa, *flavissima* and *iberiae* mainly in W, *lutea* in E; some (especially *cinereocapilla*) also remain around Mediterranean region. C & E populations migrate mainly to S Asia, some (e.g. *beema*) also to Africa; those in far E of range (*tschutschensis*, *simillima*) move as far S as the Sundas, with *simillima* regularly reaching N Australia. Races mix freely in non-breeding quarters, and N race *thunbergi* found in non-breeding season from Africa across to SE Asia. Departure from breeding grounds mainly Aug-Oct, from Jul in N, reaching winter quarters mostly in Oct; return begins Feb, some not leaving until end Apr, arrival in breeding areas Mar-May, in N sometimes not until early Jun; large passage involving at least five races through Middle East, from late Aug (*feldegg*) to Oct (*lutea*) and in spring from mid-Feb (*feldegg*) to May (*thunbergi*, *lutea*). Migrates diurnally, in flocks; adults and offspring may migrate together, although males reported as leaving wintering grounds earlier than females, and males were earlier migrants than females on four Italian islands; adult males may arrive before yearling males.
Status and Conservation. Not globally threatened. Locally common to very common; uncommon in some regions, and status of some races uncertain. Estimated European population over 7,000,000 breeding pairs; very large roosts in winter quarters, e.g. one in Nigeria estimated to contain 50,000

On following page: 61. Citrine Wagtail (*Motacilla citreola*).

individuals. Declines reported between 1970 and 1990 in 13 countries in Europe, involving mainly nominate race and *flavissima*; increases recorded in Sweden and Slovenia, and stable populations in 16 other countries. In Britain, marked decline (9·4%) noted between breeding survey in 1968-72 and that in 1998-1991. Declines have been linked with agricultural intensification, especially drainage of wetlands in floodplains and replacement of grassland with cereals; in some areas, as in E Britain, this species does breed in root crops and cereals, but at lower densities than in prime floodplain habitats. Drainage, use of pesticides and dumping of manure may have caused declines in Continental Europe. Few comparable data from other parts of range; common resident in Egypt (*pygmaea*). Recently discovered breeding in C Saudi Arabia (*feldegg*). In African winter quarters, migrants thought to be vulnerable to chemical spraying of Red-billed Quelea (*Quelea quelea*) roosts in trees or reedbeds where wagtails also roost.

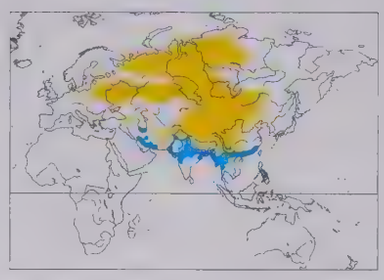
61. Citrine Wagtail

Motacilla citreola

French: Bergeronnette citrine **German**: Zitronenstelze **Spanish**: Lavandera Cetrina
Other common names: Yellow-headed/Yellow-hooded Wagtail

Taxonomy. *Motacilla citreola* Pallas, 1776, Siberia.

Has been thought to form a superspecies with *M. flava*, or with that species together with *M. capensis* and *M. flaviventris*, but such relationships not supported by recent molecular-genetic studies. Recent research, using mitochondrial DNA, suggests that W race *werae* may represent a separate species, closer to SE Asian races of *M. flava* and distinct from nominate E race, which appears closer to NE races of latter; others, however, consider *werae* to be morphologically and vocally inseparable from nominate. Further study needed. Races intergrade. Proposed race *quassitrix* (described from S Russian Altai) considered indistinguishable from nominate, and *sindzianicus* (N Xinjiang, in NW China) from *werae*; *weigoldi* (from N Sichuan, in C China) synonymized with *calcarata*. Three subspecies recognized.



Subspecies and Distribution.

M. c. citreola Pallas, 1776 - breeds N Europe (Finland, N Russia) E to C Siberia, Transbaikalia, Mongolia and NW Manchuria; winters mainly Indian Subcontinent, also SE Asia.

M. c. werae (Buturlin, 1907) - breeds E Europe (S Baltic Republics, E Poland), Belarus and Ukraine E to Russian Altai, N & E Kazakhstan and NW China (NW Xinjiang); winters Indian Subcontinent and SE Asia.

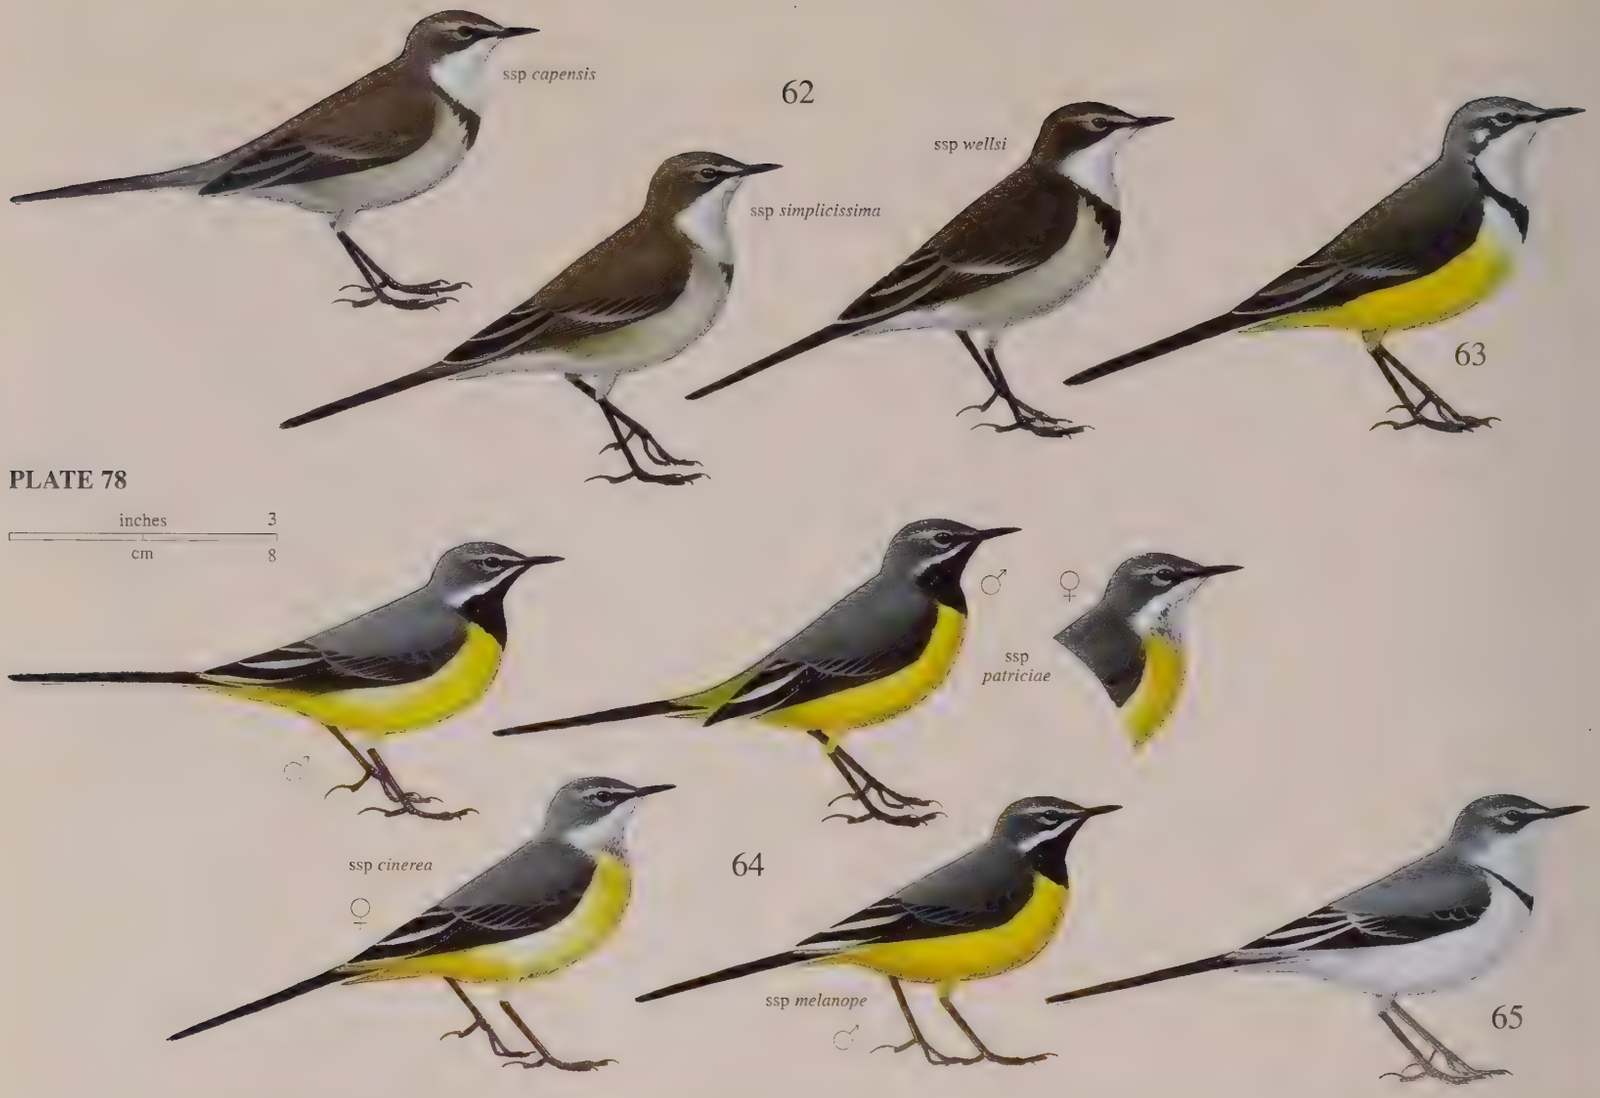
M. c. calcarata Hodgson, 1836 - breeds E Iran, Afghanistan, and C Asian mountains from Tien Shan E to C China (E to C Gansu and Sichuan) and S to N Himalayas; winters lowlands from S Afghanistan E to Myanmar.

Descriptive notes. 16·5-20 cm; 18-25 g. Male nominate race in breeding plumage has bright yellow head and underparts, black lower hindneck and upper mantle, black extending slightly onto breast side; lower mantle and scapulars dark grey, tinged olive, rump dark slate-grey, uppertail-coverts black; remiges and greater and median wing-coverts dark brown to black with pale edgings, white covert tips forming two wingbars, lesser coverts dark olive-grey; tail mostly black, outer two feather pairs mainly white with black bases; yellow of underparts washed olive-grey on side of

breast and flanks, sometimes blackish spots on breast side, undertail-coverts yellowish-white; iris dark brown; bill black; legs black or blackish-brown. Non-breeding male is duller, hindcrown to mantle and scapulars dark olive-grey to grey, sometimes some dark mottling above, yellow areas paler. Female resembles non-breeding male; non-breeding female is duller, greyer above, yellow areas paler, grey on side of breast and flanks, whiter on belly. Immature has little or no yellow in plumage, is more buff and more grey than non-breeding female, olive-brown on breast side and flanks. Races differ mainly in colour tones of breeding male, but much individual variation: *werae* male differs from nominate in having purer grey back with no dusky suffusion, paler below with less grey on flanks, female is similar to nominate, on average slightly smaller; *calcarata* male differs in having all-black upperparts, deeper yellow of head and underparts extending to undertail-coverts, edges of tertials broader and purer white, greater coverts often all white, often more black on inner webs of outer two rectrices, female is similar to nominate but may show diffuse blackish spots on mantle to rump, more blackish uppertail-coverts, has more yellowish-tinged undertail-coverts, on average longer bill and tarsus. Voice. Song, from bushtop or in flight, 2-4 simple notes, first note often sharper, repeated in phrases separated by several seconds; rather similar to that of *M. flava* or *M. alba*. Call a distinctive wheezy or husky, rather harsh "peep", "zeet", "dzeep" or "drreeep" or disyllabic "tit tit"; also higher-pitched and less rasping "pzeeoow".

Habitat. Favours marshes, edges of lakes, willow (*Salix*) thickets and wet rough grassland in tundra, also areas of willow bushes on mountain meadows and sometimes in fields near villages. In non-breeding season similarly wet habitats, including also coastal marshes, brackish lagoons, sewage farms and irrigated land, wet paddyfields, lake margins and riverine sandbars; in Nepal favours wetter areas than those used by *M. flava*. Breeds from sea-level to 4600 m.

Food and Feeding. Food includes wide variety of invertebrates, often aquatic, and their larvae; recorded items include, among others, nymphs and adults of dragonflies (Odonata) and beetle larvae (Coleoptera), adult and larval flies (Diptera), and spiders (Araneae). Forages by picking and darting for prey; takes items from the ground, from low vegetation or from water surface. Walks on open wet ground at edge of water and on floating mats of aquatic vegetation such as water hyacinth (*Eichhornia*); wades in shallow water. Will also flutter up to snatch an insect in air.



Breeding. Late Apr-Jun, later in N, and May-Aug in SE (*calcarata*); often two broods. Monogamous; territorial, but may nest semi-colonially. Nest, built by female, a cup of moss and plant leaves and stems, lining of hair, wool and feathers, placed on ground in grassy vegetation. Clutch 3-6 eggs, occasionally 7; incubation by both sexes, period 14-15 days, in Poland 11-12 days; nestling period 10-13 days, sometimes up to 15 days. For 28 nests in Poland, hatching success 55·3%, fledging success 38·1%, average of 1·8 young reared per nest.

Movements. Migratory. Winters in Indian Subcontinent (except S & E) and in SE Asia, smaller numbers also S shores of Caspian Sea and N Persian Gulf; occasional winterer in Middle East. Regularly recorded during spring migration in Israel and also in Oman, which may indicate that a wintering area exists in Africa; at least 15 records from Africa (Egypt, Sinai, Morocco, Djibouti, Ethiopia and Cameroon), and one straggler reached South Africa in Apr-May 1998. Occasionally occurs E to Japan. Increasingly recorded as a vagrant in W Europe since 1980. S migration mainly Aug-Oct; return N from Mar, arrival in breeding areas Mar-May, in N Siberia not until Jun. Migrates and winters in flocks; sometimes roosts together with *M. flava*, as in S Nepal (Chitwan).

Status and Conservation. Not globally threatened. Very common in tundra belt of N Russia, less common farther S; estimated total population in European Russia over 300,000 pairs. Density in preferred habitat in Ukraine 0·3-0·5 pairs/ha. In recent decades has extended its range to W & SW; regular breeder in Ukraine since 1976, breeding first reported in Belarus in 1982, in Lithuania in 1987, in Estonia in 1991, in Latvia in 1993 (six pairs in 1998), and in Finland and N Poland since 1990s; has bred in Germany and the former Czechoslovakia, and in Armenia.

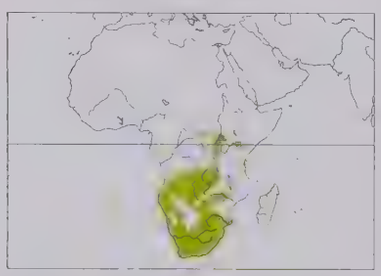
PLATE 78 ➤



62. Cape Wagtail

Motacilla capensis

French: Bergeronnette du Cap **German**: Kapstelze **Spanish**: Lavandera de El Cabo
Other common names: Angolan Wagtail (*simplicissima*); Wells's Wagtail (*wellsi*)

Taxonomy. *Motacilla capensis* Linnaeus, 1766, Cape of Good Hope, South Africa.
Sometimes thought to form a superspecies with *M. flaviventris*; both also suggested as comprising a superspecies with *M. flava* and *M. citreola*, but such a relationship is not supported by recent molecular-genetic studies. Race *simplicissima* sometimes treated as a separate species. Proposed races *bradfieldi* (from W Namibia) and *beirensis* (S Mozambique) included in nominate. Three subspecies recognized.

Subspecies and Distribution.
M. c. wellsi Ogilvie-Grant, 1911 - E DRCongo E to SW Uganda and NW Tanzania, and W & C Kenya.
M. c. simplicissima Neumann, 1929 - Angola E to SE DRCongo, S to NE Namibia, N Botswana and Zambia, and W Zimbabwe (on R Zambezi).
M. c. capensis Linnaeus, 1766 - W & S Namibia, SE Botswana, much of Zimbabwe and W & S Mozambique S to S South Africa.

Descriptive notes. 17-20·5 cm; 17-25 g. Adult nominate race has narrow buffy supercilium, dark brown to black lores; above, mainly dark olivaceous grey, wing feathers blackish-brown with buffy or grey edges; tail brownish-black, T3-4 edged and tipped white, T5-6 mostly white; chin and throat creamy; dusky pectoral band, broader in centre, breast side and flanks olive-grey, centre of lower breast and belly yellowish or creamy white, undertail-coverts white; axillaries grey, underwing-coverts whitish; iris dark brown; bill black; legs blackish. Sexes alike. Immature is warm brown above, wing-coverts tipped pale buff, underparts washed with pale yellow, has shorter tail than adult. Race *simplicissima* has more olivaceous upperparts than nominate, yellower wash on underparts, breastband reduced to an irregular spot in centre of breast; *wellsi* has darker upperparts than others, well-defined blackish pectoral band, pinkish wash below. Voice. Song a jumble of twittering notes, "tweep tweep tweep, witititi, cheep-tweep", sometimes containing phrases similar to those of a finch (Fringillidae). Call a loud, liquid, high-pitched "tseeep" or "tweep" or disyllabic "tseep-eep" or "weeep tèdèdjèj"; also drawn-out trisyllabic whistle.

Habitat. In S occurs near any sort of water, so long as open ground nearby; found around houses and gardens, farms, villages, on large areas of lawn in towns and villages, as well as by tree-lined rivers, small slow-moving streams, floodlands and pastures, dunes and both sandy and rocky coasts. In N (N of R Limpopo) much less urban, preferring wetland edges, sides of slow-moving streams, rivers and ditches, muddy edges of pools and reservoirs, sewage farms, watered lawns around houses, but also cultivations, grassland and forest clearings, to 3000 m. Occurs above 2000 m in highlands of Kenya. Communal roosts containing up to 100 individuals in reedbeds or in trees, often in busy city centres, outside breeding season.

Food and Feeding. Diet mainly insects, including flies (Diptera), often midges (Chironomidae) and mosquitoes (Culicidae) and their larvae, larval and adult moths and butterflies (Lepidoptera), beetles (Coleoptera), ants (Hymenoptera), and dragonflies and their nymphs (Odonata); also termites (Isoptera). Also crustaceans such as sandhoppers (Talitridae) and small crabs, snails (Mollusca), tadpoles and small fish; ticks (Acarina) also eaten. Household scraps, ranging from raw meat and suet to bread, cake, cheese and hard-boiled eggs, readily taken. Forages on wet mud and moist grassland, often feeding among cattle. Foraging usually involves walking and picking or darting after insects on the ground, also wading in shallow water and picking at prey in or over the water; jumping up into the air for insects. Occasionally makes short aerial sallies from trees in manner of *M. cinerea* or a flycatcher (Muscicapidae). Singly, in pairs or in family groups; in non-breeding months also in loose flocks of up to 50 individuals.

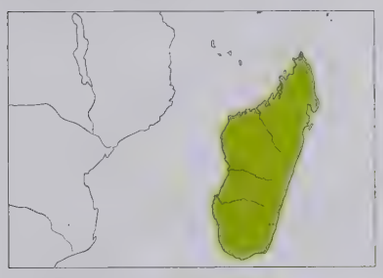
Breeding. Mar, Jun-Sept and Nov-Dec in Uganda, Jan, Apr-May, Jul and Sept in Kenya, and Jul-Aug in Zambia; lays in most months in S, season Aug-Dec (mainly Sept-Oct, occasionally Feb) in Zimbabwe, and in South Africa mostly Sept-Nov in N and Jul-Jan in E; up to six broods in a season. Monogamous, permanent pair-bond; solitary and territorial. Nest, built by both sexes, a cup of grass, rootlets and leaves, lined with finer rootlets, cattle hair and sometimes wool or feathers, concealed in vegetation on ground or in low vegetation, occasionally up to 6 m above ground in tree, bush or creepers, generally over or close to water. Clutch 1-4 eggs, exceptionally 5-7; incubation by both sexes, period 12-14 days; chicks fed by both sexes, nestling period 15-16 days; juveniles fed by both parents for 3-4 weeks after fledging, injury-feigning display by adults when newly fledged young present. Nests regularly parasitized by Red-chested Cuckoo (*Cuculus solitarius*) and Diederik Cuckoo (*Chrysococcyx caprius*).

Movements. Largely sedentary; some wandering in parts of E Africa, and in parts of South Africa and Zambia possibly a long-distance altitudinal migrant or partial migrant. Post-breeding dispersal or hard-weather movements may account for observed increases in numbers at some places in dry winter months; marked influx in Botswana during dry season, suggesting regular seasonal movement. Outside the breeding season may form flocks, and roosts communally (up to 100 birds) in reedbeds or in trees, often in busy city centres

Status and Conservation. Not globally threatened. Frequent and widespread; most common in parts of S. In E Africa common in SW Uganda, but scarce in E DRCongo, Rwanda, Burundi and N Tanzania; local and uncommon in Kenyan Highlands. In South Africa, density on R Little Caledon (Free State) 3·2 pairs/10 km, and total of 21 pairs along 65 km of river; 31 counted in the intertidal zone on Dassen I (off Western Cape) in Nov. Sometimes concentrated in a small area, e.g. a few hundred pairs found in relatively small area around freshwater pools at Sandwich Harbour (Namibia). Population in S Africa decreased in 1950s and 1960s as a result of insecticide use, but has since recovered. Has probably benefited from creation of artificial environments, such as parks, garden lawns, sewage farms and dams.

Bibliography. Anon. (1979), Beel (1992), Begg (1981), Benson *et al.* (1971), Berry (1980), de Boer & Bento (1999), Brewster & Tyler (2002), Bunning (1998), Clancey (1963, 1964b, 1996), Dean (2000), Earlé (1986e), Every (1973), Furlong (1999), Ginn *et al.* (1989), Godfrey (1925), Hanson (1999), Harrison *et al.* (1997), Herholdt (1986b), Hewitt (1964), Hockey *et al.* (1989), Irwin (1960, 1981), Jensen & Vernon (1970), Johnson & Maclean (1994), Keith *et al.* (1992), Kopij (1997), Lewis & Pomeroy (1989), Mackenzie (1982), Mackworth-Praed & Grant (1960, 1962), Milton & Dean (1999), Neumann (1929), Nevill (1984b), Oatley (1988, 2002b), Oschadleus (1996), Parker (1999), Parker & de Boer (2000), Penry (1994), Prozesky (1963), Rowan (1983), Short *et al.* (1990), Sinclair & Davidson (1995), Sinclair & Hockey (1996), Sinclair *et al.* (1993), Skead (1954), Stevenson & Fanshawe (2002), Steyn (1996), Tarboton (2001), Underhill (1992), Van Ee (1963), Venter (1999), Voelker (1999c, 2002), Wilson (1999), Winterbottom (1959a, 1968).

63. Madagascar Wagtail



Motacilla flaviventris

French: Bergeronnette malgache **German**: Madagaskarstelze **Spanish**: Lavandera Malgache

Taxonomy. *Motacilla flaviventris* Hartlaub, 1860, Bombetoke Bay, Madagascar.

Sometimes thought to form a superspecies with *M. capensis*; both also suggested as comprising a superspecies with *M. flava* and *M. citreola*, but such relationship not supported by recent molecular-genetic studies. Described race *icterica* (SC Madagascar) considered indistinguishable from other populations. Monotypic.

Distribution. Madagascar.

Descriptive notes. 19 cm. Large wagtail with narrow black breastband. Male has grey crown and nape, prominent narrow white supercilium, dark grey eyestripe and moustachial stripe; rest of the head grey, small white crescent under eye, whitish spot on ear-coverts; upperparts mouse-grey, more olive on rump and uppertail-coverts; wings blackish-brown, remiges white basally, tertials fringed white, whitish tips of greater wing-coverts (indistinct wingbar); tail blackish-brown, outer rectrix white; throat and underparts white, strongly washed lemon-yellow on belly and flanks, narrow black band on upper breast extending around throat side to join moustachial stripe; iris brown; bill blackish; legs dark grey. Female and immature are paler than male. Voice. Song, from ground or perch or in flight, a trisyllabic, slightly trilled melodious "tree treeoo", usually repeated several times, followed by melodic phrase; more complex song by presumed male when he brought food to female on nest. Call a buzzy "trrree trrree-oou", frequently repeated, sometimes followed by melodious "tsee-eee-wee-oo tsee-wee-oo", in flight, on ground or perched.

Habitat. Open areas near water, whether fresh, brackish or salt; typically, by lakes and rivers, in marshes, paddyfields and fish ponds, and on beaches. Also away from water in clearings in woodland, in secondary forest and gum (*Eucalyptus*) plantations, cultivated areas, and around dwellings in towns and villages. Sea-level to 2600 m.

Food and Feeding. Diet mainly small invertebrates, notably insects and spiders (Araneae). In brief study at one nest, caterpillars and moths (Lepidoptera), as well as unidentified insects, and a lizard, were brought to the nestlings. Food items obtained largely by picking while walking jerkily or running on the ground; sometimes flutters up to snatch an insect in air.

Breeding. Breeds Aug-Nov; two broods. Record of juvenile from first brood joining parents in feeding nestlings of second brood. Nest a typically bulky structure, with neater cup of twigs, stems and mosses and lining of finer material, built in low bush, fork of tree, rock crevice or depression in boulder, or under house roof, often near or over water. Clutch 3-4 eggs, usually 2; incubation by both sexes, period not documented; chicks brooded and fed by both parents, female may take larger share of brooding, male delivers more food to nest, feeds nestlings directly or passes food to mate for brood-feeding, nestling period at one nest 15-16 days; at same nest, male sang as he brought food, female then left nest and perched beside mate, latter displayed by cocking tail almost vertically and fluttering closed wings rapidly, then slightly spread wings while shaking the body and singing, female then left and male fed chicks.

Movements. Some internal movements occur, but details unknown. Appears to leave the High Plateau during austral winter, presumably moving down to lower-lying ground.

Status and Conservation. Not globally threatened. Common and widespread, occurring throughout Madagascar. Most common in E and on the High Plateau; less numerous in N & W, rare in S. Has possibly benefited from presence of humans; frequent around houses, even in well-populated areas, and utilizes artifical habitats for foraging and artificial structures (house roofs) for nesting.

Bibliography. Bangs (1918), Benson (1981), Benson *et al.* (1976-1977), Dee (1986), Greiner *et al.* (1996), Koenig (2002), Langrand (1995), Milon *et al.* (1973), Morris & Hawkins (1998), O'Daniel (1997), Rand (1936), Sinclair & Langrand (1998), van Someren (1947).

64. Grey Wagtail

Motacilla cinerea

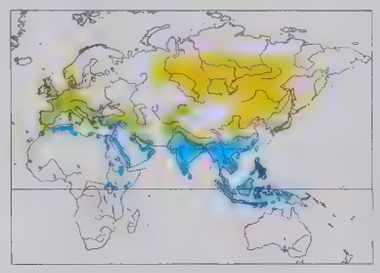
French: Bergeronnette des ruisseaux **German**: Gebirgsstelze **Spanish**: Lavandera Cascadeña

Taxonomy. *Motacilla Cinerea* Tunstall, 1771, no locality = Wycliffe, Yorkshire, England.

Relationships uncertain. Sometimes thought to form a superspecies with *M. clara*; possibly closer to E forms of *M. flava*. Variation clinal, tail length decreasing gradually from W to E, and E individuals on average darker, but differences relatively minor and much individual variation: E races *melanope* and *robusta* possibly better merged with nominate. Similarly, birds from Turkey, Caucasus and Iran sometimes treated as race *caspica*, but appear indistinguishable from nominate. Six subspecies tentatively recognized.

Subspecies and Distribution.

M. c. cinerea Tunstall, 1771 - British Is and N, W & S Fennoscandia S through much of W Europe to Iberia and islands in Mediterranean Sea, NW Africa (Morocco, N Algeria), Turkey, Caucasus and N & SW Iran.



M. c. melanope Pallas, 1776 - breeds N Asia from Ural Mts E to C coast of Sea of Okhotsk, S to NW, N & E Mongolia and E China (S to S Gansu, S Shaanxi and Hebei); also in mountains from Tien Shan S to E Afghanistan and E along Himalayas; winters NE Africa and S & SE Asia.

M. c. robusta (C. L. Brehm, 1857) - breeds extreme E Asia from E Russia (S & C Kamchatka and Amurland) S to Korea and Japan; winters S to Sundas and New Guinea.

M. c. patriciae Vaurie, 1957 - Azores (Furnas, São Miguel).

M. c. schmitzi Tschusi, 1900 - Madeira.

M. c. canariensis Hartert, 1901 - Canary Is.

Descriptive notes. 17-20 cm; male 15-22 g, female 14-20 g. Distinctive; the only long-tailed wagtail with blue-grey upperparts and yellow uppertail-coverts and underparts. Male in breeding plumage has narrow white supercilium and eyering, black lores, white moustachial stripe; top and side of head grey, upperparts grey, olive-yellow rump and uppertail coverts, upperwing-coverts olive-grey; remiges black, inner ones edged white; long tail black, outer three rectrices white; chin and throat black, rest of underparts bright yellow; underwing grey, white bases of flight-feathers; iris dark brown; bill black; legs pinkish-brown or dark flesh-brown. Non-breeding male differs in having chin and throat white or buffy white, supercilium buffy. Breeding female differs from male in having chin and throat buffy white, mottled black, sometimes all black; non-breeding female differs from male in paler yellow underparts, more buff on breast. Immature is similar to non-breeding female, but pale markings more buff, dark markings more olive. Race *melanope* is somewhat darker and shorter tailed than nominate; *robusta* is marginally shorter-tailed than nominate, on average slightly darker above and deeper yellow below, with more extensive and deeper black on throat; *canariensis* is richer yellow (sometimes more orange-yellow) below, greenish-tinged on back, white markings on face and wings more contrasting; *patriciae* is darker grey above, particularly on cheeks, white supercilium only behind eye, shorter tail with less white on outer rectrix; *schmitzi* is similar to last, but has shorter bill, less black on tail. Voice. Song, in flight, a series of notes as "tzii-tz-tzi-tzi-tzee-ree-ree-ree", ending in trill, given as the male parachutes down from a tree or wires to the ground. Call a sharp "chittick", "tzitzi" or "si-heet", similar to that of *M. alba* but higher-pitched, more metallic and staccato; alarm a rising "sueet".

Habitat. Fast-flowing mountain streams and rivers with riffles and exposed rocks or shoals, often in forested areas; also more lowland watercourses, even canals, where there are artificial waterfalls, weirs, millraces or lock gates. In non-breeding season frequents wider variety of habitats, including farmyards, sewage farms, forest tracks, tea estates, and even town centres. Breeds at up to 4100 m in Himalayas.

Food and Feeding. Prey mainly insects, notably fly larvae and adults (Diptera, especially Chironomidae) and nymphal and adult mayflies (Ephemeroptera) and caddis flies (Trichoptera); some dragonflies (Odonata), moth caterpillars and adult butterflies (Lepidoptera), beetles (Coleoptera), lacewings and alderflies (Neuroptera), bugs (Hemiptera), grasshoppers (Orthoptera); freshwater shrimps (*Gammarus*), terrestrial snails (Mollusca) and spiders (Araneae) also eaten. In India, three stomachs contained 28 flies, 10 bugs, 7 grasshoppers, 6 beetles, 3 dragonflies and a spider. Of 944 prey items retrieved from nestlings in Czech Republic, 90% comprised flies, mayflies, stoneflies (Plecoptera) and beetles in equal proportions, while caddis flies and homopteran bugs each comprised just over 3%, and other items included insects (Lepidoptera, Hymenoptera, Orthoptera, Neuroptera), spiders, crustaceans and gastropod snails; almost 69% of food items were adult insects, but prey taken to nestlings varied according to weather. In a second study in Czech Republic, flies comprised 36% of 496 prey items, stoneflies 26%, homopterans 13·5% and caddis flies 8·5%; aquatic insect larvae represented less than 7% of nestling diet, although they were more important earlier in breeding season when there were more large larvae in the river (as the season progresses, the adults emerge). In C Asia, nestlings at L Baikal were fed a range of insect prey, as well as spiders and terrestrial molluscs, but 54% of items were, in order of abundance, mayflies, stoneflies, flies and caddis flies; in Tien Shan Mts mayflies, stoneflies and caddis flies dominated the nestling diet in late Jun and early Jul, accounting for 85% of food items, but comprised only 5·4% in late Jul, when dipterans (32·8%) were most important. Forages by walking and picking, run-picking, and flying up a short distance from ground to catch an insect; also makes flycatching sallies from a perch out over water, this technique being more frequent in summer months when temperatures are high and aerial insects more active. Also wades in shallow water to pick aquatic prey.

Breeding. End Mar to Aug, mainly from Apr, in Europe; late Mar to May in N Africa, early Mar to Jun in Canaries, lays from from late May in Azores; end Apr to early Jul in N Indian Subcontinent; frequently two broods, occasionally three. Monogamous; highly territorial, linear territory 200-1000 m or more. Male has parachuting display-flight, descends from tree or overhead wire, wings lowered and spread, tail depressed and yellow rump feathers conspicuously puffed up, singing until it reaches ground. Nest, built by both sexes, a typical platform and cup of coarser material, lining of finer grasses, root fibres and usually horse hair, placed on rock ledge or in crevice in riverbank, or often on ledge in wall, under bridge or in drainpipe. Clutch 3-7 eggs, usually 4-6; incubation by both sexes, female taking larger share, period 11-13 days; chicks fed by both parents, both also remove faecal sacs, nestling period 11-13 days; injury-feigning distraction display by adult when flushed from nest with young; young attended and fed by both parents for 2-3 weeks after fledging, sometimes by male alone if female soon lays a second clutch. In Europe, 42-63% of eggs produced fledged young, and productivity as high as 3·3 young per nest in Germany.

Movements. Island races and S populations resident; others partial or long-distance migrants. Nominate race winters in S parts of breeding range and in N Africa and coastal Arabia; some

On following page: 65. Mountain Wagtail (*Motacilla clara*).

continue S to W & E Africa, a few reaching DRCongo, Malawi and Tanzania, occasionally farther S (Zambia, Zimbabwe, Namibia, South Africa). E populations migrate to NE Africa and S Asia, winter widely from Indian Subcontinent E to SE China, and Taiwan and Philippines, race *robusta* extending S to Sundas and New Guinea (and recorded also in New Britain and Australia). Present throughout year in Japan. In many areas, individuals make short post-breeding movements to habitats that provide better foraging opportunities during winter months; for example, many descend from uplands to low-lying wetlands and farmland. Migrants leave breeding grounds from Aug onwards, often not until Oct; return in Mar-May.

Status and Conservation. Not globally threatened. Frequent and widespread in mountainous areas, and common in most of range. European population estimated at c. 1,000,000 pairs; abundant in Azores (20,000 pairs) and common in Madeira (300-500 pairs). Expansion of range recorded in Scandinavia and parts of C Europe during 20th century. Adversely affected by harsh winters in W & C Europe; suffers population losses in prolonged spells of severe cold weather. Has probably benefited from human activities on lowland rivers, exploiting fast-flowing water near weirs and on mill streams, and utilizing walls and bridges as nest-sites. Appears to be little affected by stream pollution.

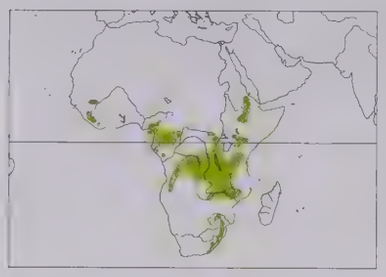
65. Mountain Wagtail

Motacilla clara

French: Bergeronnette à longue queue **German**: Langschwanzstelze **Spanish**: Lavandera Clara
Other common names: Grey-backed/Long-tailed Wagtail

Taxonomy. *Motacilla clara* Sharpe, 1908, Simien Mountains, north Ethiopia.

Initially named as *M. longicauda*, but that name invalid, as preoccupied. May form a superspecies with *M. cinerea*. Race *chapini* possibly inseparable from *torrentium*. Three subspecies recognized.



Subspecies and Distribution.

M. c. chapini Amadon, 1954 - SW Mali, S Sierra Leone, Liberia and W Ivory Coast, and from SE Nigeria and Cameroon S to Gabon and E to Central African Republic and N & S PRCongo; also Bioko I (Fernando Póo).

M. c. clara Sharpe, 1908 - highlands of Ethiopia.

M. c. torrentium Ticehurst, 1940 - E Uganda, C & S Kenya, and from E & S DRCongo, Rwanda and NW & N Tanzania S to C & SW Angola (S to Namibe), Zambia, N Zimbabwe and W Mozambique, also in mountains of E South Africa and Swaziland.

Descriptive notes. 17-19 cm; male 15-21·5 g, female 15-24·5 g. Graceful, long-tailed wagtail with much white in tail. Has narrow white supercilium ending just behind eye, blackish lores and area below eye, dark grey ear-coverts; otherwise mostly grey above, wings blackish, most remiges and wing-coverts narrowly edged white, tertials broadly edged white; central three pairs of rectrices black, T2 tipped and sometimes edged white, T3 with white inner web edged black, outer three pairs entirely white; white below, greyer on flanks, narrow black breastband (broader in centre); axillaries and underwing-coverts white, outer primary coverts black; iris dark brown; bill black, base of lower mandible sometimes greyish; legs pinkish-brown or greyish-brown. Sexes alike.

Immature differs from adult in absence or near absence of breastband, sometimes has buffy suffusion on underparts. Races differ little: *torrentium* has broader white borders of tertials, shorter wings and proportionately longer tail than nominate; *chapini* has marginally darker upperparts than previous. VOICE. Song a quiet, sustained series of trilled musical phrases and short notes, "ti-tuu-ui-tui-tui" or "tsrrrrup, tsrrrrup, tsrrrrup...", usually regularly repeated phrases, and quite varied. Call a loud, metallic, disyllabic "chirrup" or "chizzik" or high, drawn-out "sreeeeeeh" or "treeedrurrup", given on taking flight or as contact; alarm "phweep" or "chweep".

Habitat. Fast-flowing, rocky forested streams and rivers in lowlands and mountains, to at least 2000 m; altitude not important, so long as there is a steep gradient to provide waterfalls, cliffs, exposed rocks and rushing water. May occur in more open situations, especially in areas where *M. aguimp* is absent.

Food and Feeding. Mainly insects such as flies (Diptera), especially midges (Chironomidae) and empids (Empidae), blackflies (Simuliidae), also nymphal and adult mayflies (Ephemeroptera), dragonflies (Odonata), caddis flies (Trichoptera), stoneflies (Plecoptera), beetles (Coleoptera), and butterflies and moths (Lepidoptera); also other small invertebrates; small fish and tadpoles also eaten. Of 304 items found in faecal samples in one Ethiopian study, chironomid and empid flies formed 53%. Dragonfly nymphs were prominent in diet in a South African study. Forages by picking and darting for prey on the ground or vegetation; by wading in shallow water and picking prey from in, on or over the water; by jumping up to catch insects; and by flycatching over river.

Breeding. Breeds in Jan-Apr and Sept-Nov in Ethiopia, in all months in Tanzania, in Mar and Jul-Nov in Malawi, and in May and Aug-Dec in S Africa. Monogamous; highly territorial, defends 200 m to 1 km of river from conspecifics, although non-breeding *M. cinerea* may be tolerated. Territorial and courtship displays involve tail-fanning, drooping and vibrating of the wings, and aerial chases; during courtship display, individual may walk towards its mate while holding wings drooped, body plumage fluffed, tail raised and fanned. Nest, built by both sexes, often a bulky structure, with base formed from leaves, grass, moss and roots, neat deep cup of fine rootlets and hair, usually lined with hair, usually placed on ledge on riverside cliff, in recess in earth bank or among tree roots by river, sometimes under bridge; occasionally up to 50 m away from water, as on wooden beam, under thatched roof of a shelter, at edge of dense forest; nest-site reused in successive years, even same nest reused if repairable. Clutch 1-4 eggs, usually 2-3; incubation by both adults, period 13-14 days, both also feed chicks, nestling period 14-16 days; both parents continue to care for young for up to 30 days after fledging, longer with later broods.

Movements. Sedentary on permanent streams in Ethiopia; believed to be nomadic in E & S Africa, and possibly to make seasonal or migratory movements in W Africa. A single record in Botswana may have involved a migrant or wanderer from Zimbabwe or South Africa. No evidence of communal roosts or flocking.

Status and Conservation. Not globally threatened. Frequent on suitable watercourses through much of range. Possibly occurs also in S Sudan (Imatongs) and Eritrea. No evidence of any change in status, although deforestation and siltation may have adverse effect. In Ethiopia, survives on degraded streams in open areas, even where stream reduced to a trickle with algae-rich pools, and occurs on grossly polluted streams in Addis Ababa. In urban areas of South Africa, increased runoff of storm water is causing severe erosion and degradation of streams, by both scouring detritus from pools and increasing the amount of silt deposition.

uis, Calendulauda sabota 558
ultima, Elaenia frantzii 272
Umbrellabird 102
Amazonian 102
Bare-necked *57*, *62*, 102
Long-wattled *40*, 102
Ornate 102
umbrosus, Manacus manacus 157
Unadorned Flycatcher 346
unica, Dixiphia pipra 151
unicolor, Chloropipo 160
uniformis, Chloropipo 160
unirufus, Lipaugus 38, 89
unitatis, Cecropis abyssinica 676
Unstreaked Tit-tyrant 283
Upland Pipit *698*, 754
urbicum, Delichon 619, *627*, 674
Urich's Tyrannulet 260
urichi, Phyllomyias 260
Uromyias 282, 283
uropygialis, Lipaugus 89
uropygialis, Pachyramphus major 459
uropygialis, Phyllomyias 262
uropygialis, Stelgidopteryx ruficollis 662
uropygiatus, Attila spadiceus 445
urubambae, Elaenia albiceps 268
urubambae, Ochthoeca leucophrys 383
ussuriensis, Anthus richardi 745
utahensis, Eremophila alpestris 589

V

vaalensis, Anthus 753
vagilans, Calandrella cinerea 583
validus, Myiarchus 439
validus, Pachyramphus 461
vamberyi, Galerida cristata 595
variabilis, Xenicus longipes 473
Variegated Bristle-tyrant 303
Variegated Flycatcher 416
variegatus, Legatus leucophaius 406
varius, Empidonomus 416
Varzea Mourner *120*, 168
vauriei, Calandrella raytal 586
velatus, Xolmis 237, 393
veliei, Contopus sordidulus 368
velutina, Lepidothrix coronata 147
Velvet Manakin 151
Velvety Black-tyrant *182*, 379
Velvety Manakin 147
venezuelae, Camptostoma obsoletum 275
Venezuelan Bristle-tyrant 305
Venezuelan Flycatcher 433
Venezuelan Tyrannulet 295
venezuelana, Serpophaga hypoleuca 285
venezuelanus, Knipolegus poecilurus 378
venezuelanus, Leptopogon rufipectus 308
venezuelanus, Myiophobus flavicans 346
venezuelanus, Pogonotriccus 305
venezuelense, Laniisoma elegans 76
venezuelense, Ramphotrigon megacephalum 443
venezuelensis, Atalotriccus pilaris 318
venezuelensis, Leptopogon superciliaris 307
venezuelensis, Mionectes olivaceus 309
venezuelensis, Myiarchus 433
venezuelensis, Terenotriccus erythrurus 352
ventralis, Phylloscartes 299
ventralis, Platyrinchus mystaceus 341
veraepacis, Schiffornis turdina 168
Vermilion Flycatcher *181*, 374
Vermilion-crowned Flycatcher 407
vernayi, Alauda gulgula 599
vernayi, Cecropis striolata 678
versicolor, Pachyramphus 454
verticalis, Eremopterix 572
verticalis, Tyrannus 186, 422
veseyfitzgeraldi, Calendulauda sabota 558
vetula, Muscipipra 402
Victoria Lyrebird 495
victoriae, Menura novaehollandiae 495
vidua, Motacilla aguimp 779
vieillotioides, Pyrrhomyias cinnamomeus 353
vigensis, Empidonax affinis 363
vilasboasi, Lepidothrix 140, 148
vilissimus, Zimmerius 295
villarejoi, Zimmerius 170, 296
villosus, Myiobius 351
Vinaceous-breasted Pipit 763
vincenti, Calendulauda africanoides 558
Violet-green Swallow *614*, *621*, 650
virens, Contopus 369
virescens, Empidonax 180, 359
virescens, Phyllomyias 259
virescens, Phylloscartes 300
virescens, Schiffornis 119, 168
virescens, Tyranneutes 166
viridanum, Todirostrum 334
viridicata, Myiopagis 266
viridicauda, Pipreola arcuata 80
viridiceps, Mionectes striaticollis 308
viridiceps, Phyllomyias burmeisteri 259
viridiceps, Poecilotriccus plumbeiceps 331
viridiceps, Tolmomyias flaviventris 340
virididorsale, Todirostrum cinereum 334
viridiflavus, Zimmerius 297
viridior, Chloropipo holochlora 160
viridis, Pachyramphus 186, 453
viridissimus, Zimmerius bolivianus 296
viridiventris, Manacus vitellinus 156
vitellinus, Manacus 130, *131*, 156
vitiosus, Lophotriccus 318
vividus, Mitrephanes phaeocercus 371
vividus, Platyrinchus flavigularis 342
vociferans, Lipaugus 51, 89
vociferans, Tyrannus 421
vorax, Tyrannus dominicensis 423
vulpecula, Calandrella somalica 585
vulturnus, Macronyx croceus 772

SUMMARY OF VOLUME 9

COTINGIDAE (Cotingas)
PIPRIDAE (Manakins)
TYRANNIDAE (Tyrant-flycatchers)
ACANTHISITTIDAE (New Zealand Wrens)
ATRICHORNITHIDAE (Scrub-birds)
MENURIDAE (Lyrebirds)
ALAUDIDAE (Larks)
HIRUNDINIDAE (Swallows and Martins)
MOTACILLIDAE (Pipits and Wagtails)

TECHNICAL DETAILS

- 310 × 240 mm
- 864 pages
- 78 colour plates
- 440 photographs
- 809 distribution maps
- c. 6000 bibliographical references
